"In order to determine the question with regard to the danger of eating the affected potatoes, I had none of the injured portions cut away from the tubers, on which I lived almost exclusively for three whole days; during which time I ate 8 pounds, with butter, in soup, or simply cooked in water, without experiencing any inconvenience except slight indigestion, a symptom which probably would not have manifested itself if the spoiled portions had been previously removed. Further, I have drunk in the morning, fasting, a glass (about 8 ounces) of water, in which 5 pounds of putrid tubers had been boiled. It was a yellowish-brown, turbid, and thick, but not viscous; of a slightly disagreeable smell, and nauseous taste, leaving a bitterness, which remained on the palate for an hour. I found no other symptoms of indigestion from this liquid, except a disagreeable heat oppressing the chest for about two hours. My two clerks and servant, observing that I felt no repugnance in eating these potatoes, and that no inconvenience resulted, followed my example next day, and were nothing worse. After stating the above facts, I hope the diseased potatoes will no longer be considered poisonous, nor in any degree dangerous when the decayed portions are removed. Anxious to know whether it was possible to save the sound portions of the tubers for use, I collected 100 pounds of such as were partially affected, from which I had the unsound portions completely removed. After this operation there remained 73 pounds of sound pieces, which I find as good to use as the finest of those exposed for sale. Hence, about three-fourths of the potatoes that are thrown away may be turned to good account; and I shall be happy if my experiments and observations tend to preserve a considerable portion of aliment, so precious to the poor, and of which they are in danger of being deprived by fatal prejudices.

"M. J. BONJEAN.

"De Chambery."

The next point is the mode of storing the crop. The universal opinion is, that the only practicable means of effecting this is by trusting to dryness, which is precisely what we have recommended from the beginning. The manner of securing a sufficient degree of dryness is different, but all agree in dryness being essential; and this must be so, when we consider that all the crop is more or less charged with water, which, in favorable seasons, the plants would have lost in the ordinary course of growth. Drying in *dark* chambers, well ventilated by means of a sprinkling of lime, or by dry earth interspersed among the tubers, are methods that have their advocates. We hold to the latter as being, upon the whole, the best plan: first, because it is easiest, and more especially because the disease is certainly contagious; *that* we have ascertained by the following direct experiment: Several sacks of apparently sound bread fruit potatoes, ten days since, were placed in a dry stable and covered with mats, for the sake of seeing whether they could be so kept. On uncovering them, a large proportion were already exhibiting the mouldy appearance which invariably

accompanies the disease. We have no doubt that the air is impregnated with the seeds of the fungus; that whenever it falls upon a decaying or injured surface it takes root, provided the vitality of the tuber is low; that the vitality of all potatoes from diseased districts is low this year; that, moreover, they are all more or less injured (necessarily) in the operation of digging, and that, consequently, they all offer a favorable situation in which the fungus can propagate itself. Now, if potatoes are placed in dry rooms, or packed in any other way so as to allow air to circulate among them, the seed of the fungus will reach them.

The last point to which we shall advert is the course to be taken with the seed next year.

It is clear, from the following very important communication from Mr. Grey, of Dilston, that autumn planting answers perfectly. We should, therefore, adopt that mode of cultivation at once.

COMPARATIVE PRODUCE OF AUTUMN AND SPRING PLANTED POTATOES.

Your number for November last contained the detail of an experiment which I made last year on the growth and produce of potatoes planted in October and in April, the result of which was, that the plot planted in April, on the same land and with the same manure as the other planted in October, gave 86 loads per acre—the seed having been from large potatoes cut in two—and that planted in October, with the like seed, gave 111 loads; whereas small potatoes, planted whole in October, gave 100 loads.

In October last I prepared my land, and planted my potatoes in drill rows of 30 inches width, applying fold-yard manure below the sets, but leaving three rows unplanted for each intermediate month between October and April, inclusive. The land is a strong loam, except at the upper end, where it touched for a few yards upon clay, in which the potatoes failed to a great extent in all the plantings. At the low end of the rows, the land is good and perfectly uniform. The manure and treatment of all were alike in every respect, except as to the times of planting. This year I did not apply guano in the spring, as detailed in the experiments of last year. None of the potatoes have been affected by disease; but the earliest planted showed the greatest strength and vigor in the stems, although there were occasional vacancies in the rows. The land was all drilled up in October, at which time the largest part was planted. Three rows more were dunged and planted in like manner in the end of November, and three in the end of December. In January and February the weather was so bad, and the frost so hard, that no planting could be accomplished. Three rows more were planted early in March, and the remainder of the land at usual time of planting in April.

The potatoes have been taken up within the last three days; and, to test the comparative produce of the several plantings, my man began at the low end of the rows and dug onwards till he had filled a sack which contains ten stones weight. The contents, however, is immaterial, so long as the same sack was used for all. The average length of the drill rows required to fill the sack—

Of October	planting, was	30	yards,
Of November	do	32	do
Of December	do	32	do
Of March	do	44	do
Of April	do	45	do

which leaves to the October planting an increase of one-third over that of April; a result not very different from that of last year, in which the quantities were 111 to 86. From this it would seem that it does not much signify at what period in the winter potatoes are planted, provided the land be free and dry, and the weather suitable for working it; but it is evident that a loss of power is sustained by allowing the seed to remain in pits till the spring, under a slow process of vegetation, when, before being used in the field, considerable shoots have already been put forth, wasting the nourishment which is requisite to sustain the plant in its early growth, and before it begins to derive its support from the soil. A few more such experiments may tend still further to elucidate this important subject.

JOHN GREY.

Dilston House, *October* 16.

If small sound potatoes, or such as are very slightly affected, are now exposed to the light, they will rapidly become green, and their vitality will be so much raised as probably to enable them to resist all decay. If such greened tubers are cut into sets, they should be sprinkled with powdered lime, or otherwise dried by exposure to air for two or three days, and then planted. Of course, in a case of this kind, where every thing is new, it would be unsafe to affirm that this process will be effectual. But it holds out so good a prospect of success, that we do not hesitate to recommend its immediate adoption. It has, also, this advantage—that if it should fail, potato fields can be again planted in the spring.

It will be well to select for the crop new ground; and, if possible, high, dry situations. But while we state this as a matter of prudence, we have no confidence in its necessity. Our own opinion is, that if sound seed are used, no fear need be entertained of the mischief appearing another year.

After giving this subject the most serious attention, we can arrive at no other conclusion than that the disease is to be traced to the peculiar circumstances of the season—that is to say, to atmospheric causes, and to nothing else; that the mischief produced by the mildew fungus is quite a secondary circumstance, although probably a serious aggravation of the original mischief, and that nothing is to be feared from it hereafter, unless the same atmospheric conditions should occur.

CAUSE OF THE POTATO MURRAIN.

It appears to me that the disease primarily attacks the stem, and I think the view I take of the subject holds good in some cases, if not in all. I maintain that it is a disease of the fluids: the descending sap becomes poisoned by the generation of unwholesome gases in the stem; from the excessive moisture prevalent through this season, the proper exhalation of the plant has not been carried on; thus, we find that the stem undergoes decomposition instead of gradual decay, and this deteriorates the descending sap, which, passing to the root, poisons, as it were, the tubers. My own potatoes, which were planted on new ground, on a very steep slope, are not in the least affected. Where they were grown on higher ground, the

tops died early, and the tubers are as healthy as possible. Before the last rain I dug about a rood, both from the lower and higher ground, and all were equally sound. A few rows remained, which I was prevented by the rain from digging up: these I have since gathered, and they have shown symptoms of disease; the tops were fine; but after the rain, they were all matted together. During their growth I never saw tops have a more luxuriant appearance; clear and fresh, with nothing like specks on the leaves or stems.

Another thing which causes me to consider the sap as poisoned, is the great rapidity with which the tubers decay. They appear healthy, from all outward appearance; still, in many cases, if they are stored away, the specks are manifest—first, of a dingy hue, then darker colored, and afterwards becoming soft and rotten. Had the leaves or stems of my potatoes shown any sign of specks, I would have pulled the stems out of the ground, leaving in the tubers awhile before I dug them up; this would have prevented any bad effect from a deteriorated sap. A proof might be obtained by comparing the analysis of an unsound potato with that of a sound one. I think we should find, at any rate, the ultimate elements to be in different proportions to what is usual.

A. B., *M. R. C. S.*

The potato disease appears to be similar in nature to the smut and other diseases that affect wheat. Is it not, therefore, probable, that the same remedies that are found effective to preserve wheat may be advantageously employed in the case of potatoes? Experience has shown that certain steeps (blue vitriol, for instance) effectually prevent the ravages of smut. I would, therefore, suggest that the experiment should be made, whether soaking potatoes intended for seed in solution of blue vitriol might not probably destroy the vegetative power of the fungus on the potatoe, without affecting the vegetative power of the potato itself. Of course, the poisonous nature of blue vitriol makes this suggestion inapplicable to potatoes intended for any other use except for seed. I cannot help being strongly of opinion that the disease is not of such recent origin as is commonly supposed. Any one who will examine the columns of the *Chronicle* many months before the harvest of 1845 was begun, will find numerous complaints of partial failures of the potato, and suggestions as to the cause. I think it is now scarcely possible to doubt that the same cause was then in operation which has since produced such terrible effects.

I know two instances, in 1844, in which nearly the whole crop was worthless; and, though I have had no particular description of the appearance of the potato, I do not doubt the disease was the same as has since become so prevalent.

P. P.

It is worthy of remark, that whereas Mr. Paxton considers the disease to be "principally confined to what are called the early potatoes," in this neighborhood the early crops were as good, if not better, than usual. When attention was first called to the existence of the disease, I thought it ad-

visable (as a precautionary measure) to take up a considerable quantity of the early kinds for seed, although they were scarcely ready; and after being properly dried and "greened," they were carefully stored, and are still perfectly sound and good. I find that the pink-eyed varieties are much more susceptible of infection than the white and rough skinned kinds.

J. L. SNOW.

BEDALE.

To the Editor of the Morning Herald:

SIR: The disease in the potato crop having become so general, and the results so disastrous to the community, will, I trust, be my best apology for offering to the public the results of my chemical experiences to endeavor to neutralize the ravages of this lichen in the plant. The disease presenting a similar appearance to the *porigo lupinosa* in the human scalp, induced me, by analogy of treatment, to try the effects of mild alkalies, which succeeded only to a partial extent, but sufficiently to encourage me to employ a solution of caustic soda, and this I found invariably put a stop to any further progress of the parasite vegetation; consequently leaving the potato in a sound, healthy state, and fit for food.

The method to be used is simply to prepare a solution of caustic soda, equal in density to 8 degrees of Beaumé, and immerse the tubers for about half an hour; then drain and thoroughly dry them by exposure to the sun and air, and store them in chaff or cut straw.

I am, sir, your obedient servant,

A. LINDA.

ST. HELIER'S, *October* 25.

To the Editor of the Morning Herald:

SIR: I have to request the favor of your giving insertion to the enclosed letter of Mr. Tattersall, of Grosvenor Place. Chlorine is easily made by mixing three parts of salt, one of manganese, and two of oil of vitriol, in an earthen vessel. Many bushels can be disinfected at an expense of a few shillings.

Your obedient servant,

HENRY REECE.

MEDICAL HALL, 168, *Piccadilly.*

"GROSVENOR PLACE, *October* 23.

"DEAR SIR: I examined the potatoes submitted by you to chlorine, and then kept in a warm, dry place. The potatoes were from my farm at Willesden. When the crop was first taken up, more than one-third of them were thrown away as good for nothing. Soon after, the others began to decay. Those sent to you were all infected with the prevalent disease; they are now completely healthy. In one, where the disease had previously destroyed two-thirds of the potato, the decay had been stayed; a clear line of demarcation was established between the healthy and diseased portion,

which had quite dried up; the bad smell was entirely gone. The potato, when cut open, was sweet and healthy, though the entire portion which the disease had spared could not have been a third.

"The remedy is so cheap and simple, and a large quantity may be cleaned with so little trouble, that I think it ought to be made known to the public. I placed my potatoes in three layers on hurdles in a close room, and then applied the chlorine. With many thanks for the trouble you have taken,

"Believe me yours truly,

"E. TATTERSALL.

"H. Reece, Esq."

THE POTATO DISEASE.

To the Editor of the Norfolk News:

Sir: A person in this town had accidentally left a potato last spring in the corner of a closet in his house, which the other day was found with *seven small potatoes* attached to it, and *five out of the seven are spotted with the murrain*, so fearfully prevalent throughout the Kingdom. It must be something more than excessive wet, or cold, humid atmosphere, which occasioned this evil, for they grew in a perfectly dry place.

Yours, &c.,

GEO. JULER.

North Walsham, *October* 30.

THE DISEASE IN THE POTATO CROP.

To the Editor of the Morning Post:

Sir: A circumstance has occurred here, which may perhaps be useful to farmers if they should again be visited by this disease. On the first appearance of the complaint in the potato haulm, a small field belonging to the Rev. Mr. Sergison, of Cuckfield Park, adjoining the church-yard, showed indubitable signs of being attacked. It was almost the first piece that was affected, and, as it had been planted with potatoes for twenty-eight successive years, it was supposed to arise from the continuous cultivation of one species of root. As the fence dividing it from an adjoining meadow was only a double post and rail, a quantity of two toothed sheep that were turned into it after mowing broke into the potatoes, and fed off the haulm, eating it off closely, with the exception of the upright or main stalk.

This was supposed at first to have done some good in staying the disease; but, as the stalks were closely shaved and shortly died, no more was thought of it until last week, when the potatoes were lifted, and found, with the exception of a few that were rotten in the ground, and a few bushels that showed signs of having been attacked by the disease and were in a state of decay, to be perfectly sound, and in a fit state for storing.

The ground is of dry soil, of a sandy loam, and the potatoes planted were of the Shaw variety.

This goes far towards proving that the disease originates in the haulm, and demonstrates the utility of feeding off or cutting it when first attacked.

It was the only piece of backward potatoes that has escaped in the neighborhood.

As I have long been a subscriber to your entertaining and useful paper, I have sent you the above, to insert or not, as you may think proper.

Yours, &c. &c.,

S. SERGISON.

CUCKFIELD PARK, SUSSEX, *October* 31.

THE POTATO DISEASE.

To the Editor of the Times:

SIR: I regret that further observation of the pared and sliced potatoes I mentioned in my speech at Birmingham, in which, for a few days after I had dried them in the sun and air, the growth of the fungus seemed stopped, has convinced me that the disease is again going on; so that unless the slices be made as dry as biscuits, in a slow oven, or on a fire or malt-kiln, at a heat sufficient to kill the fungus, its growth will go on, and destruction of the potato follow.

I see it recommended to steam or boil all potatoes in which the smallest speck of decay has appeared, and to ram them down air-tight in casks, or large jars or pans, covered over at the top with a layer of fat, to be kept like potted meat, for use during winter, and stored in a dry place. This seems to be the easiest mode of preserving potatoes in every stage of decay short of absolute rottenness.

I yesterday asked some eminent machinists to contrive a small and portable boiler, by which steam may be introduced to the bottom of casks set on end and filled with potatoes. They suggested that a Papin's digester, having a small lead pipe fixed in the centre of its lid, may be inserted into casks of every size, in which a false bottom of wood should be placed under the potatoes, at a few inches from the bottom, sufficient to allow free passage to the steam. A similar lead pipe may be fixed on the top of any large teakettle or common boiler; and if this top be tied down with wire to prevent its being blown off by the steam, this steam will fill the cask, and in the usual time boil or steam the potatoes, and, killing the fungus by heat, will stop its further progress.

The fungus matter thus boiled is wholesome and nutritious, being not a putrid substance, nor a murrain or gangrene, but only another kind of vegetable, formed from the substance of the potato, and, like eatable mushrooms, is good for food.

It is only where the potatoes are absolutely rotten that I would advise the preparation of starch, which alone remains after all the membranes and tissues of the potato are consumed by fungus. This may easily be done by crushing, stirring, and washing the pulp several times in tubs of *cold* water, in which, at the end of every stirring, the starch will separate from the pulp and fall to the bottom of the tub.

I think that steaming in large casks, or boiling in the common way, where there is no contrivance to make steam, is much better than grating the decayed potatoes in any stage short of rottenness; when they are rotten, the starch still remains, and is all that can be saved.

The potatoes thus steamed or boiled may be stored in casks of any size,

from sugar hogsheads to butter firkins, and a little salt should be sprinkled on the potatoes as they are put into the casks; but it is essential that they should be *rammed quite close and air tight throughout*, and that the top and bottom of the casks, and every joint and crack, should be rubbed over and filled with grease or pitch. If this be done, the potatoes will keep like meat and vegetables potted in air-tight tin cases, which are sent to India and back quite fresh.

Where there is time to pare the potatoes before steaming or boiling, this should always be done, and the parings, *boiled*, given to hogs and cattle.

As large potato steaming vessels exist, or may in a few days be placed in all the union houses in the country, the inmates may be most advantageously employed in steaming and ramming potatoes into casks, while the inhabitants of each neighborhood are occupied in bringing their potatoes and empty casks, and carrying them away full of food thus rescued from destruction.

I am, sir, your obedient servant,

W. BUCKLAND.

OXFORD, *November* 7.

P. S.—It is essential that the casks or pots be kept in some place *perfectly dry*. Where cottagers have no such place, farmers and proprietors will assuredly lend them lofts or barns, or stables or outhouses.

From the Preston Pilot.

THE POTATO CROP.

An intelligent correspondent, who has bestowed considerable pains to ascertain the state of the prevailing disease in potatoes, has favored us with the following results of a promiscuous survey or inspection of the potato crops in the townships of Woodplumpton, Broughton, Barton, Inskip, &c., and gives the following cases:

1. An old ploughed field, planted with varous kinds; about a tenth part of the whole very rotten. Had this crop proved sound, the produce would have been an average. Soil of a hazel nature.
2. A newly broken up field, usually called "Ley Backs," well drained, and well cultivated. Soil between hazel and black, planted with "kemps," an early sort. About one-third rotten, and the remainder rotting fast after dug. Had all been sound, this crop would have been a deficient one.
3. A very old ploughed field, say thirty to forty years. Soil rather black, planted with early kinds. Manured with guano. All, or nearly all, sound; but rather a light crop.
4. A nice dry croft, ploughed a few years. Soil very free and black, and very clean from weeds; planted with "blues," and half rotten.
5. A good field. Soil, "bastard black," well manured and cultivated. Many kinds, but mostly "blues" and "jackies," or "cups." Greater half gone, and the remainder going fast.
6. A high and dry bed, delved in a meadow. Kind, "jackies." Nearly all rotten, and bad in every respect.
7. An old broken up field. Soil, hazel. Many sorts, and nine-tenths rotten.
8. A very stiff, heavy, wet soil. Two and a half acres, planted with

"Kendal Kemps," "blues," and "Royal Georges." The return good, and all free from disease, excepting a few of the last named description.

9. Excellent land. Soil of a fine, free, black nature, particularly well manured and cultivated. This was by many considered the most flourishing crop in the neighborhood. A great deal prove rotten, and altogether deficient.

10. Two acres. A newly broken up soil, of a blackish nature, and admirably cultivated. Crop fair, and about one-twentieth part rotten; the rest going so fast, the farmer is selling them off at 2s. 6d. per load.

11. Fine free soil, broken up four years ago. When got up, sound to appearance, but the disease destroys them immediately afterwards. Planted both early and late kinds.

12. Fine, dry, sandy soil, in excellent heart. Sound when gathered; but selling them as fast as possible, from fear of their all going rotten, as he can pick out a great quantity every day beginning to look black and wet. Before either the wet weather or frost came, this farmer got up a quantity, thinking of their being seed next year. He had them dried, greened, and well hogged; and on examining them, he found every potato more or less affected.

13. High, dry land, near a railway, commonly called "Spoil Banks." Sound to appearance, but fully expected to go bad.

14. Very old "foughten" land, well manured and attended to. Planted with early kinds, and many going rotten.

15. [This gentleman is a sientific and practical agriculturist.] Dug up part of an old meadow near to a brook; manured one part with his own midden dung, and the other with night soil. The drills were made with the spade, and the manure put in at the time. Planted many kinds—amongst the rest, half a load of "Kendal flat reds." These he planted whole sets, excepting a few from which he cut a small piece from the haulm or tail ends. He then shook them up in a sack containing gypsum; and when he planted them in the drills, he put some more gypsum upon them, previous to covering them up. He has not more than threescore pounds back from the half load, the remainder being rotten. The other kinds were also diseased. He also planted some new sort, raised by himself from crabs, two years ago; and finds the produce neither greater nor sounder than from old seed. He dug some "lemon kidneys" early in the season, for seed another year; and on examination, finds them going rotten.

From the above cases, he makes the following remarks: It does not appear that the crops in old, hard-worked soils are any worse than those in fresh broken up fields, although this is contrary to all precedent and experience. It also seems that the black, free, sandy, or likely soils, have not done any better than the stiff, clayey, or unlikely grounds. There does not appear to have been any want of care and attention on the part of the farmers, either as regards draining, manuring, or keeping weeds down. In some of the crops of early potatoes, the leaves dropped from the stems early in the season, the stems keeping their erect position, but assumed a yellowish appearance, an evident sign of the disease having commenced its ravages. This was not the case with the backward crops, which maintained their freshness and vigor until cut down by the frosts. Taking the Fylde district through, it may be safely asserted that fully one half are now completely rotten; and it is generally considered the remainder will not keep.

ANSWERS TO QUERIES.

To the Rev. A. M. Forrester, minister of the parish of West Linton:

The general crop has suffered to a certain extent in almost every instance from the prevailing disease, both by rotting in the ground and after being raised. It is worthy of particular remark, that in many instances, where lifted early in small quantities for use, *and before the decay of the shaw, or foliage more particularly*, the portion of the crop so lifted appeared, and proved, on cooking, to be perfectly sound and healthy; whereas, on lifting the remaining portion, *in the same field*, some time after the shaws had decayed, they turned out to be tainted, like the general crops of the country. However, by being housed, and frequently aired by the door being left open, and in pits, care being taken to lift off the covering every good day, for a while, to air and dry the mass, under both these plans of treatment the disease appears to have been at all events temporarily arrested.

It is also worthy of remark, that on hanging land, looking north, and where the crop was late planted, and in vigorous growth till near the period of lifting, having thus enjoyed the protection of the shaws, a foliage covering, which aided materially in defending the tubers from the heavy rains, acting in some measure as a natural roof, casting aside the wet into the furrows, they turned out, upon lifting, to be scarcely affected at all. In this instance, not only did the shaws cast off the rain into the furrows, but the land having a considerable inclination, the superabundant moisture escaped by the furrows to a lower level, leaving the surface and crops comparatively dry. But even here, wherever the superabundant moisture was collected in any slight depression, or hollow, the disease appeared to some extent.

In another instance, on undulating land, the depressions forming natural cups, or basins, retaining the water as it fell, and affording no means of escaping, *in the same field* the potato crop was excessively damaged in these natural hollows, whilst the more elevated or shelving parts were comparatively unaffected. In one instance, however, the crop raised off dry land was stored in pits early, and, on opening the pits, the potatoes were found to be a decaying mass. In this instance, however, the crop was raised in very wet weather, stored wet, and of course in bad order for keeping sound.

In another instance, a portion was raised in a field soon after the decay of the shaws, when a very considerable number indeed appeared to be diseased; sometime thereafter the number increased; and within a week, and after the heavy October rains, *when the crop had ceased growing, and had been for some time exposed without the protection of the shaws*, more than a third of the crop was found to be damaged. After raising, too, the loss was considerable, although the diseased tubers were carefully separated.

On dry and level ground, *with an open bottom*, the loss was not so great as under less favorable circumstances. On level ground, *with a retentive sub-soil*, the loss was great. On inclined ground, *where the crop was late planted*, and *particularly if inclining to moss*, the loss was often inconsiderable.

It would appear that the potato crop had this year suffered severely from the cloudy and extremely cold and wet season; the temperature, especially in high districts, frequently bordering on frost, so early as from the latter end of July to the end of August, and subsequently; and the white and most delicate kinds have suffered most. Such a season was ill adapted for bringing this crop to maturity (scarcely a seed apple having appeared in this local-

ity during the past season,) and was undoubtedly eminently unsuited to the constitution of the potato plant, derived as its original was, and acclimated, from a dry and sunny country. This is undoubtedly the cause of the prevalence and severity of the *rot*, which is the disease affecting the present crop. There is, therefore, no such cause for serious alarm; on the contrary, there is every reason to expect, if the tubers are planted next spring which shall have resisted decay during the ensuing winter, and if next spring, summer, and autumn should prove warm, sunny, and dry, and propitious to the maturation and storing of the potato crop, that the produce will, despite the present visitation upon us, prove sound and abundant. There is no rational reason for anticipating the contrary. I do not apprehend there will be the slightest danger from using tubers for seed, which shall have resisted decay during the winter. It has been ascertained that the potato crop is not affected in the more warm and sunny countries of Europe, which is a pretty convincing proof that the cold and cloudy skies which have prevailed over great parts of Europe and America during the past season have been, along with any accidental constitutional weakness in the plant itself, the predisposing and active cause which has generated, extended, and aggravated the disease of rot, depending, or rather resulting, in a great measure, in active, followed by putrefactive fermentation, before lifting, or consequent on storing, more particularly where that operation has been carelessly or improperly performed.

No doubt *after decay of the shaw* the chief damage has been received. It would then, *at least*, daily become more apparent; and may be, so far, familiarly accounted for, as it has been found to operate thus. *In the first place*, so long as the potato crop retained the shaws, or haulm, it was in vigorous growth, and was capable of resisting the unfavorable influence and action of superabundant moisture during the late wet season. *In the second place*, the shaws acted as a protection from the rains, as I have already said, casting them aside into the furrows, leaving the cup, *where perfectly earthed up*, high and dry above. And, *in the third place*, it may be remarked, that on the decay of the foliage covering of the shaws, not only were the drills left exposed, but from the extraordinary prevalence and violent action of the high winds, accompanied by heavy rains during the late season, cups or small depressions were formed on the top of the drills, *at the root of every shaw*; and the interstices or openings left, *on the decay of the shaw*, leading from the surface of the drills down to the tubers, and forming, in fact, natural pipes or conductors *from the several cups formed on the surface down to the tubers*, would act in this way. The cups would *receive the rain-water as it fell*, and the pipes, *left by the decay of the stems*, *would conduct* the moisture received and collected in the cups *directly down to the tubers*, and keep them constantly wet; and they have thus been lying, since the decay of the shaws, in *the very circumstances, and under the very conditions, and exposed to the very influences*, most favorable for inducing rot, which is, without doubt, the only disease with which the potato crop has this year been so severely affected. No doubt, as I have already said, the sets might have been predisposed to disease; because, so to speak, the constitution of the plant has been for some years deteriorating in the country. But had the late season been a genial season, as it was the reverse, the probability is, that the injury would have amounted to nothing more than has been usual in an average of past seasons.

The progress of the disease has not ceased or abated, *where the tubers*

have been stored wet, or in bad order, or without reasonable precautions. Few attempts at remedy have been ventured. But I would remark, generally, that when housed, where there is the necessary accommodation, the tubers should be examined frequently, picked carefully, and where obtainable with little trouble or cost, they may be beneficially sprinkled with gypsum, slacked lime, dry peat ashes, or even with the roughly dried sand; and though exposed with the doors open for air during the day, they must be carefully covered with abundance of straw, and the doors shut during the night. The use of *either of the first three substances* will have a very excellent and healthful effect in preventing the noxious gases arising from the mass injuriously affecting the individuals employed in picking, sorting, and turning the tubers. * * * It would appear, from all experience, that *perfect dryness and thorough ventilation are the only efficient attainable remedies or curatives, or preventives.* * * * It has been remarked elsewhere, however, and observation in this locality seems to confirm it, *that a soil of bog or peat earth,* very prevalent in this quarter in particular localities, *seems to have a very decided and sensible effect in preserving the crop free from the prevalent disease. This may be of great importance next spring at seed-time.*

I am, dear sir, yours truly,

JAMES ANDERSON.

22 Hill st., Edinburgh, *Nov.* 10, 1845.

From the New York Farmer and Mechanic.

NEW YORK FARMERS' CLUB.

In the County Cork Agricultural Society, of which Lord Barnard, a member of Parliament, is president, this subject [potato rot] was recently considered. Prof. Allman spoke of the deep anxiety felt on the subject, and of his examinations made by powerful microscopes. He says that he was enabled to see the organic arrangements of the potato by cutting off a thin transparent portion, placing it on a bit of glass, laying a drop of water over it, with a small portion of the tincture of Iodine, covering it with another bit of glass, and using a microscope of *three hundred lineal magnitude* A quantity of starch would be detected lying on its cells, and the starch globules would be seen in their exact proportion, and would be colored by the Iodine. The starch would be seen distinct from every other substance in the potato. It would be seen that the healthy cells were full of starch, while the diseased potatoes were very deficient. The disease appeared to prevent the formation of starch in the young potato; and when it attacked the old potatoes, the starch being already formed, might be extracted for food. He recommends grinding up the potatoes and extracting the starch.

John Dillon Croker—Had examined disease in England, and was "horror-stricken, on returning to Ireland, to find that the angel of destruction had smitten the crop of this country." Some had said that the severe frost of the 7th of September had been the cause, but he had dahlias, geraniums, and French beans, which were bright and green, while the potatoes were gone; frost was out of the question. He had put some potatoes into scalding water by way of trying an experiment, but in these the plague-spot showed in an hour, and the potatoes rotted rapidly. He said that we must get the starch out; that the starch in the diseased potato was just as good as in the sound ones. He said, "Let Ireland from henceforth become a

consumer of good wholesome *breadstuffs.*" He said the starch of the potato could be eaten as we eat arrow-root, and what we get from the shops by that name is made generally of *potato flour*, and which is passed off under a dozen names as an important and nutritious diet.

Mr. Smith, of Layham—Had extracted from five bushels of bad potatoes thirty pounds of flour, and had refused to sell it at sixpence a pound. A bushel of potatoes would yield eleven or twelve pounds of flour.

In Kilkenny and Athlone, potatoes were produced weighing from two and a half pounds to *five pounds* each, and there was no disease in them.

A mode of preserving potatoes from disease after being dug, is recommended, viz: sift in lime over them until every potato is coated.

Some districts are free from the potato plague. It is said that the *white-eyed* potatoes have escaped the disease almost entirely.

It is stated that the *apple potatoes* are *not one-fifth of them sound;* the *dukes* nearly as bad; the *cups* pretty safe; and that the only potatoes which have escaped entirely are some *early Scotch;* that the *kidneys* are pretty free from disease; that the potato disease is contagious; that the healthy ones must be carefully separated from those diseased.

PRESERVATION OF THE POTATO CROP.

To the Editor of the Mark Lane Express:

I first fix upon a piece of ground as high and dry as I can select. I then mark out five feet in width, and of any length that may be required, cutting a trench round the same, and with the excavated earth still further advancing the ground wheron the potatoes are to rest. Upon that bed I spread a thick layer of clean dry straw, on which is put a thin layer of potatoes, as free from dirt and loose moulds as I can conveniently make them; then another covering of straw, succeeded by a second layer of potatoes; on these I place rows of rough tiles, two feet apart crosswise—that is, from side to side—by which flues are formed for the escape of the damp; and thereon I advance the hill with potatoes to any height that may be found convenient. Such being effected, I again resort to straw; but stubble, thin-pared sods, or any similar material, would answer the purpose nearly as well, which I spread pretty thickly over the whole of the potatoes, and then cover them down with earth for the winter. To prevent damage being done by the frost, I plug up the ends of the tiles every night with wisps of hay, removing them every morning, which should be attended to until the potatoes are found to be in perfectly dry condition. I lately opened a pie wherein I had put promiscuously, on the above plan, potatoes damaged and sound, wet and dry, which had been covered down with earth nine days. To my great satisfaction, I found the potatoes quite free from heat, much dryer than when stored, and those which were diseased in a far more healthy condition, the damaged parts having changed into dust, the wounds having become in a great measure incrusted over, and apparently, from the best judgment I could form of them, likely to prove good and wholesome food for man, and fit for seed next spring. In reference to the tiles being placed upon the second layer of potatoes, I would observe that they may be passed through any part of the pie which might be thought likely to admit of a greater portion of atmospheric air; for, in my opinion, it is the free circulation of air through the whole mass of potatoes which acts so beneficially.

Should no straw be at command to put at the floor of the pie, I would recommend tiles, as has already been described, being placed across the same at the top of the raised foundation. These, I have no doubt, would be sufficient to prevent any damage being done to the potatoes by the damp of the natural earth.

I am, sir, your faithful servant,

WM. SKIPWORTH.

SOUTH KELSEY, *November* 15.

The following practical statement, made by Mr. Croker at the meeting of the Cork Agricultural Society, is very valuable, as it may be adopted with facility in any family:

	Farina, or flour, dry and fit for use. lb.	oz.	dr.
One weight (20 lbs.) of sound white potatoes will produce	3	9	0
One ditto unsound, and diseased part cut off	3	1	0
One ditto unsound minions	3	1	0
One ditto unsound and paired	3	0	0
Unsound, none cut off	3	6	0

Diseased potatoes, useless, quite soft, and rotten, will make as good starch as the soundest, and need not have the bad parts cut off; let care be taken to have them well washed, to prevent earthy particles mixing with the flour. He would give accurately what the six loaves of bread produced are composed of, the cost of each, and the weight, by which it would seem that actually the people had it in their power, at a trifling expense, to procure from diseased potatoes a far better description of food than that they had heretofore been using; and he trusted that what was considered the greatest calamity that could befal them may prove to be a rich blessing, viz: the change of diet from potatoes to bread.

No.	What composed of.	Price of wheaten flour or oatmeal.	Weight of loaf.	Price.
1	One pound fine wheaten flour, and one pound of farina.	18*s*. 8*d*. per cwt., or 2*d*. per lb.	2 lb. 10 oz.	2¼*d*.
2	Half a pound of fine flour, and one pound of farina.	18*s*. 8*d*., or 2*d*. per lb.	1 lb. 10 oz.	1¼*d*.
3	One pound of household flour, and one pound of farina.	15*s*. per cwt., or about 1½*d*. per lb.	2 lb. 13 oz.	1¾*d*.
4	Half a pound household flour, and one pound of farina.	Do. do.	2 lb. 15 oz.	1*d*.
5	One pound of oatmeal, and one pound of farina.	13*s*. cwt., or less than 1½*d*. per lb.	2 lb. 5 oz.	1¾*d*.
6	Half pound of oatmeal, half pound of household flour, and half pound of farina.	14*s*. per cwt., or 1½*d*. per lb.	2 lb. 0 oz.	1¾*d*.

Remarks.—The cost of soda, sour milk, and salt, is included, but no allowance for fire, as the potatoes, if sound, should be boiled, taking the same quantity, if not more, than baking the bread.

The proportions were, for the above loaves a small tea-spoonful of soda, the same as salt, which must be very well blended with the flour or mixture, after which it should be let lie, wet, and worked up with sour skimmed milk, or buttermilk—the latter he preferred; and the longer kept, the better, as the sourer the milk was, the more it acted on the soda and made the bread rise better. As all country-women know how to make potato-starch, he need only say to them, provide at once a good grater or two, and set to work on the unsound potatoes. Keep your families constantly employed in picking out the diseased ones, thus securing an ample supply of the best food from this description, when the starch is sufficiently washed.

From Frank & Millard's Commercial Traveller.

After making considerable allowance for the exaggeration which usually attends statements calculated to create alarm, it seems absolutely certain that a disease has very extensively shown itself among potatoes of the present year's growth, and that the effect of it will be to reduce the crop very far below an average, and in some districts to create considerable difficuly, if not actual starvation and distress.

It becomes, then, a matter of no ordinary importance to determine by what means such an evil may be prevented for the future, as well as mitigated in its present operation.

The disease itself, in plain language, may be called the "rot," and is found to exist more or less at all times, but, of course, it only excites public attention when sufficiently extensive as to become a public evil. The existing cause of it, the writer believes to be an excess of cold and moisture. The potato is a vegetable which naturally absorbs a vast quantity of water, and, when supplied with this element in excess, it requires a proportionate degree of warmth to enable it so to assimilate the moisture it has imbibed as to convert it into a healthy substance; and in case of its wanting the degree of warmth necessary to stimulate its secreting organs into a due state of activity, it will become subject to morbid formations, and these, unless means are adopted to prevent their development, will sooner or later show themselves by that corruption, or rottenness, which, during the present season, has been so prevalent. This disease, then, sustains to the potato a similar relationship to that of scrofula to the human body; and, like this scourge of the human species, it may be considered as partly resulting from constitutional defect, and partly from external causes. Among the various opinions which have been hazarded respecting the causes of the malady, some have supposed the existence of an external "blight," by which the tubers have become ultimately affected; and others have talked about "fungi" upon the tubers, by which they have become diseased. The writer believes that the plant has become diseased through the unhealthy state of the roots or secreting organs, and that the "fungi" have resulted from the disease, and not been the occasion of it. What, then, are the likeliest means for preventing the malady in future? As far as weather

is concerned, it is clear we can do nothing but to submit to whatever may happen. We can neither command the sun to shine, nor dispose of the drops of rain, nor order the courses of the winds. Still, much remains in our own power, and which may be all summed up in a few words: the true secret of success in growing potatoes, as well as other vegetable productions, is *to sow good seed in good ground;* and whenever this simple and rational rule is neglected, there will most assuredly be more or less of loss and disappointment.

With respect to *soil*, the potato delights in that which is moderately light and porous, which points out the necessity of draining all heavy and wet lands, if they are expected to grow potatoes. In the next place, the potato requires a frequent change of soil, and on this account heavy crops are usually produced on newly broken up lands. In kitchen gardens and cottage allotments, where the root is grown year after year on the same spot, this necessity is in some measure provided for by the large quantity of fresh manure which is commonly used. Extremely favorable seasons will counteract, to a great extent, the disadvantages of the soil; but no man has a right to expect a large and healthy crop who plants his seed in land exhausted by frequent cropping, which has not been well worked by the spade or plough, or which is retentive of cold and excess of moisture.

With regard to *seed*, common sense tells us it ought to be in the highest state of perfection in which it can be obtained, and to such perfection the writer considers the following items indispensable:

1. *It ought to be whole.*—The practice of cutting potatoes into pieces for seed, leaving one or two eyes in a piece, cannot be too strongly deprecated. The result of repeated experiments has unanswerably proved that the plan has nothing to recommend it but a penny-wise and pound foolish economy. It is true that every eye possesses the germ of a perfect plant, the same as the eye of a dahlia; but every cultivator of this flower knows that, although he may get a well-formed plant, and handsome flowers, from a single eye, or the cutting of a dahlia, he only gets a good crop of *roots* from a perfect tuber. The grower of potatoes wants roots, not flowers, and to secure these let him plant whole potatoes; and for many reasons, into which the writer cannot now enter, he will find it answer his purpose better than cutting them.

2. *It ought to be in a state of maturity.*—Unripe seed is necessarily deficient of the vigor requisite to put forth and sustain a healthy plant; and, as we have already shown, whatever is a cause of weakness is a predisposing cause of disease. This is as true among vegetables as animals; and in regard to the latter, no one ever thinks of disputing it. The potatoes for planting should, therefore, be selected when the stalks have decayed, and not sooner.

3. *It ought to be of medium size, and well formed.*—The writer has ound that, on the whole, potatoes of the size of hens' eggs have produced ne neaviest crop out of a given weight of seed. He would, however, prefer *sets* much smaller, if ripe, whole, and well formed, to pieces cut from arge potatoes. The overgrown tubers should always be rejected, as containing an excess of moisture; whereas the strength of the future plant resides in the solid part of the root.

4. *The potato should frequently be raised direct from the seed contained in the potato apple.*—Every sort of vegetable propagated in the way potatoes are usually produced is liable to degenerate; and in propor-

tion to their degeneracy, they become liable to disease. Many sorts of potatoes once in common use, have become completely worn out, and their names are almost forgotten; and the writer has little doubt that much of the disease and failure which every year, and in unfavorable seasons in particular, attends the potato crop, is owing to sets being planted which are too far removed from the original seed. The vegetative principle has become too feeble to give existence to a healthy and vigorous plant; and the consequence has been those diseases to which there has been a predisposition, or which the soil or season has been calculated to produce.

5. *It ought to be well preserved.*—The best of seed may be injured by bad management; and, although potatoes will stand much rough treatment, like all things possessing life, they cannot be injured with entire impunity. When taken up they should be exposed to the air for a few days to dry and harden, by which means they will be less liable to shoot before the time of planting; they should then be stored away and effectually guarded against frost and damp. A worse plan cannot exist than allowing the potatoes to shoot, and, after pulling off the shoots, to plant the potatoes for seed. The man who is guilty of such folly deserves to lose his crop for his pains.

Much more might be said on the growth of this valuable root, but the experience of the writer justifies him in saying that, if the few rules he has here laid down were but generally observed, the same quantity of land which is now devoted to it would yield at least a third more produce, and that it would very rarely happen that the crop would fall far below an average.

From the Cork (Ireland) Advertiser, October 9.

POTATOES.

A curious fact has been stated to us by a person in the neighborhood of Carriagline. It is, that having planted potatoes in alternate beds of sea-weed and farm manure, the potatoes in the latter are entirely destroyed by the prevalent disease, while those planted in the beds covered with sea-weed have escaped untouched. The proportion which the infected bear to the healthy roots varies. In some places the destruction seems almost complete, and the progress of the disease is so rapid that in many others it threatens to become so. Even after brought home and housed, the potatoes are attacked. Several people who purchased in the market last week, and found them excellent for a few days, have since been obliged to throw the remainder out, so that it is impossible, from present appearances, even to guess at the quantity which may ultimately be secured for an acre or a field.

From the New England Farmer.

THE DISEASE OF THE POTATO CROP.

From a paper recently read before the Highland Agricultural Society of Scotland, we extract the following, without, however, adopting the author's theory of the cause of the disease:

"The first symptom of the degeneracy of the potato plant in Scotland appeared about the year 1780, when the distemper called the *curl* first appeared in the crop; but it occurred so rarely that very little notice was taken of it; but the evil gradually and extensively increased; and, about the years 1784–85, the whole crops of the Lothians were seriously affected by it. A remedy, however, was accidentally discovered, by changing the seed for that from the high country; and this has been the only remedy for the curl, up to the present time. From 1835 to the present year (1845) the seed has had to be changed yearly, as it was found a new disease appeared in the fields. This was called the *wet* and *dry rot;* and, in many instances, seed from all situations, high and low, has now failed. These two kinds of disease are variously accounted for. Some ascribe the cause to maggots and flies feeding upon and destroying the seed plants; but this is a consequence, and not a cause, for maggots and flies are only to be found on diseased or putrid vegetation. Plant a sound potato in a good soil, and, properly treated, it will find its way to the surface, and produce a good crop in defiance of all maggots and flies. The seeds of disease, then, must be in the constitution of the plant.

"In examining a diseased potato, it is plain that there is canker on the skin and plague spots all over it. This, if planted, will certainly be attacked by maggots and flies; but the plant is in a state of decay or putrefaction, and hence it belongs to them by right of inheritance. The great object, then, is to plant sound seed. As the crops on the highlands are early checked by frost, and the tops or haulm soon destroyed, they do not fully ripen; and this circumstance has induced farmers in the low districts to take up their crops for seed in a green or unripe state, in order to imitate the operations of nature on the hill grounds. But this plan has also failed. Seed has often been raised from the ball, but in two or three years it curls and degenerates.

"In looking at the origin, general history, cultivation, and general management of the potato plant in this country, I have been led to the conclusion that there can be only one cause for the failure of the plant, viz: *over-cultivation.* The crop too often repeated on the same soil, and too much stimulus applied to the plant, has weakened or destroyed its vital energies, and rendered it incapable of reproduction. In the cultivation and general management of the plant, we have entirely lost sight of nature, which always follows the moderate or middle course; and, by a long train of mismanagement, we have nearly lost this most valuable root. Who can contemplate a luxuriant crop of growing potatoes in full bloom, but must reflect on the immense stimulus applied to produce such a mass of stem, foliage, and blossom, and, at the same time, how much the roots or tubers must be enfeebled and exhausted in producing it?" * * "I would advise the experiment of topping or cutting the potato tops with a sickle about the time of the decay of the blossoms, in case the tops are too luxuriant. This will not only prevent their seeding, but check the luxuriance of the stems, and save the tubers from exhaustion. It is well known that turnip-rot is produced by excessive manuring; and I have long entertained the idea that smut in wheat, barley, and oats has always arisen from over cultivation. Every farmer has gone upon the principle that too much stimulus could not be applied to his crops; but the degeneracy of the seed or root has not been thought of."

We observe that in this country neither the rot in potatoes nor the smut in grain can be attributed to excessive manuring—that's sure.

From the London Gardeners' Chronicle, Nov. 15.

THE POTATO CROP.

I have sent you three potatoes which are evidently nearly decayed by the prevailing disease, to show that it has in no way injured their vitality; they are self sown—at least were left in the ground when the crop was taken up last August and September, when I perceived them affected, but not ripe. I let them lie on the ground, exposed for a few days, and then pitted them quite dry, in the usual way, picking out all that appeared affected, examining them occasionally. Last week I thought it advisable to throw all out of the pit, and have now laid them out in heaps in a dry loft, well covered with straw. Out of about eighty bushels about two bushels are bad, no doubt; but if they had remained in the pit, most of them would have been lost. Those decaying I found mostly breaking from the eye, and some producing, as would appear, a young potato, as you will see by one sent you. Those I had planted at the same time; and on examining them this morning, I find that they remain the same as when put into the ground, with no appearance of disease spreading. I have this week been planting about three-fourths of an acre. I in general dig the ground, and plant in each row as I go on. After planting the sets, I cover them with coal ashes: this answers two purposes—it keeps them dry, and also prevents slugs and wire-worm from injuring them. I have potted some similar to the sample sent you, and have placed them in a cool house. It will, then, be seen before the planting season whether a diseased potato will affect the succeeding crops—a thing well worth ascertaining. I should say, instead of destroying the most injured tubers, if a seed bed is thrown out, and the potatoes planted so as not to touch each other, all those that had grown would be fit next spring to be planted out in the usual way. This would be an experiment worth trying, for no doubt seed potatoes next season will be expensive to buy, if it be possible to get them at all.

T. MALLESEN.

CLAREMONT.

—

I have just thoroughly examined seven lots of potatoes of different varieties, which were stored away for seed on the 12th of September last, in charred earth, old tan, and saw-dust, charred together, and I am happy to say that the result is most satisfactory; not one tuber is to be found the least affected by the disease; and the putrid spots are so entirely dried up, that when rubbed they crumble or fall out; the other portion of the tuber is quite sound and of good quality. A neighbor of mine purchased a load of dry turf ashes, among which he stored about 25 cwt. of potatoes about a month ago, almost every potato at the time of storing being more or less affected with the disease; this day he turned them over, and brought me a sample, which is sound and dry, and the disease is entirely stayed—not one decayed tuber is to be found amongst them; when cooked, they are mealy and well tasted. Of a lot that I spread thinly on a dry floor for seed, I have been obliged to throw away above two-thirds, and the remaining portion is good for nothing: those were apparently sound when they were stored, and had been exposed for some time on a dry pavement to harden. The fungus which attacks the affected tubers runs over them very quickly—indeed, like wildfire. Charred refuse, or well burnt dry earth, or turf, or peat ashes, will at once stop the progress of the disease. I have long been

satisfied that any of these will prevent the progress of fungi; they even prevent mushroom spawn from speading. I this season planted a piece of ground which had never been manured nor cropped previously to my knowledge, with different kinds of potatoes, with a view to prove, if possible, which was the best and most valuable manure among several kinds, which I applied by weight, &c., and the result is very interesting. While the tubers produced from one particular compost were fine in quality, and not in the least diseased, others of the same variety, but manured with different material, were affected to a serious extent, though they were all growing on one piece of ground. A quantity of these tubers, free from disease, were stored in the usual way, viz: covered with straw and earth. I opened the pit and looked over them, and they are still perfectly sound.

JAMES BARNES.

Bicton.

—

I premise that my opinion—which, however, I state with some diffidence—is, that the proximate cause of the malady is the superabundance of juice or moisture in the tuber, in consequence of the excessive wet of the season, causing an accumulation of watery sap, and the concurrent frigidity of the weather, which preventing the due development of the stem and leaves, and causing their premature decay, did not afford an abundance of healthy foliage for exhaling that superfluous moisture. My potatoes were grown on very flat clay land, which, though recently thorough-drained, had not yet been sub-soiled so as to permit the free descent of the rain water to the drains; and the weather was very wet at the time of lifting, which was unduly accelerated by the prevailing panic from the supposed destructive progress of the "disease." In these circumstances, I had the potatoes carted to a lea field, intended to be broken up next year, for the convenience of a clean surface to spread them on, and obtaining sod for temporary covering. There they were laid in long narrow heaps, the different kinds separately, and covered with straw slightly "drawn" and put on thatchwise, the weather still continuing damp. This covering resisted both rain and moderate frost. On examination, a day or two afterwards, the windward side of the heaps appeared well dried, but the other side sweating and beginning to mould—the interior still more so; they were then uncovered on a dry day, spread out on the grass on either side, and put up again at night as before.

On a second examination, they were found still tending in a small degree to sweat. The same process of spreading out was repeated, after the tendency to sweat disappeared, and the progress of the "disease" to all appearance arrested. The same was the case with some of the worst of the affected potatoes, which were spread on a barn floor and turned till dry. We have been unable to find, on repeated examination, that the disease in the roots so treated has made any further progress.

Among the variety of opinions that have been given as to the constitutional deterioration of this valuable root, which seems to have rendered it more easily affected by atmospherical observations, my idea is that it has been gradually brought into what the medicos call a plethoric state, by too much forcing with manure in high conditioned land. In former times the potatoes were taken from the field and stored in cellars and other places in vast mounds, reaching from the floor to the ceiling, without injury; and the winter work was to cut the seed potatoes months beforehand, which at the time of planting were dry and shrivelled like corks. If this opin-

ion be just, the remedy would be to plough the manure (in very moderate quantity) into the ground before winter, and even to attempt to raise without manure, in fine dry soil, a small, compact, hard tuber, as a means of renovating its constitutional vigor. I mean to try both these plans myself.

In conclusion, I may mention the practice of Mr. McBride, a farmer in this quarter, who says he has followed it for many years, and has never yet had the smallest failure in his crop. He spreads the manure on the surface of his stubble land and ploughs the land, planting the potatoes in every third furrow, and drawing in with the hoe a little of the manure above the sets. I think that the potato suffers in the culture by the fibres being injured by overmuch working in the drills while in a growing state.

J. STEWART.

HEPBURN.

From the Gardeners' Chronicle and Agricultural Gazette, Nov. 22, 1845.

POTATO DISEASE.

The mere fact of dryness and coldness being recommended for the preservation of the potato, would render it more than probable that heat and moisture had in the first instance caused the disease.

That such conditions were in existence in the soil cannot be doubted; and as there can be no question about moving sap being only living sap, it really would seem that the stem of the potato was dead to all intents and purposes; so far at least as the tuber's connexion with it was concerned. The hygrometrical condition of the tuber, with the heat and moisture that were shut up about it in the soil, appears to have made it what it unfortunately is.

JOHN CAIE.

CAUSE OF POTATO MURRAIN.

That this disease is occasioned by a fungus in the leaf I have no doubt, and such, I believe, is the public opinion in general. I am equally well assured that the gangrene, or mortification, is a mere consequence of the fungus.

If, then, a certain predisposition in the potato plant, occasioned by an advanced state of the elements themselves, were alone necessary to give unbounded scope to this fungus, how, I would ask, has it happened that this strange condition of atmosphere has never occurred before since the introduction of the potato from South America—now, I believe, nearly 200 years? or shall it be said that the disease is indeed new to Europe?

On looking over the weather registries for the month of August, I find that the southwest, west, and northwest winds prevailed the whole of the month, and even extended into September; and this is, I should conceive, an extraordinary direction with regard to their continuity. Now, supposing the fungus in question to be of American origin, and new to Europe in general, is it too much to suppose that, by the continuous action of the Atlantic gales, the sporules of the fungus may have been precipitated by showers condensed from American mists? Whatever the cause be, it is to me tolerably plain that, from the breadth and uniformity of its character,

as well as the simultaneousness of its operations, it must be attributed to a cause as general as either wind, or rain, or electricity itself. Everybody has seen, according to the old phrase, "motes dancing in the sunbeams." Now, as to the sporules of various fungi, why may it not be possible for them to possess so little specific gravity as to be lighter than their own volume of air; to ascend thereby, in common with mists; to be incorporated with the clouds; to traverse thousands of miles in a few days; and to descend as propagandists wherever the winds choose to carry them, or condensation may take place?

In conclusion, I beg to say that I would not attempt to repudiate the idea of predisposition altogether, but merely direct the attention of the public to facts probably equally important.

R. ERRINGTON.

OULTON.

The tubers from which the plants have been raised this year were ripened last year in a season of almost unparalleled drought; and it appears to me that, to a certain extent, those tubers must have been assimilated (if I may use the expression) with a state of soil and atmosphere belonging almost io a tropical climate. This year the plants raised from them have had to contend with a season exactly the reverse. We know that, under particular circumstances, seed will entirely alter the nature of the plant, as regards its hardihood and time of ripening, according to the circumstances in which it is grown. Winter wheat, by being sown a few years in succession in the spring, becomes a spring wheat. Barley, on the contrary, by being sown before winter, is enabled to stand weather the most severe; the same with beans.

May not the same result have taken place with the potato tubers of last year's ripening? Would they not, in all probability, have succeeded in a hot summer better, perhaps, than those planted last summer? whereas, having had to bear all the vicissitudes of a wet summer, they have constitutionally failed.

A SUBSCRIBER.

From the Gardeners' Chronicle and Agricultural Gazette, Nov. 29, 1845.

THE POTATO DISEASE.

Salt seems to have an injurious effect, and to accelerate the growth of the fungus, or at least the decomposition of the tubers. I immersed some in a solution of salt and chloride of lime, and found them grow worse most rapidly.

The tendency of the bad potatoes to sprout is very remarkable. I have seen them lying on the ground with shoots four or five inches long, and with a healthy thickness which would make them very valuable in the spring season. In every way it is evident that the root has not degenerated, for some of the sort which the late Mr. Knight raised from the seed were as much affected as the oldest sorts. I have found a sprinkling of quick lime arrest the growth of the fungus, except where the decomposition of its substance has penetrated deep into the interior of the tuber. Immersion in

water acidulated with sulphuric acid produced the same effect, and preserves in a remarkable way the white color of the cut surface of the potato; but, with this treatment, it does not boil well for the table.

L. VERNON.

HARCOURT.

POTATO DISEASE IN CENTRAL AMERICA.

At the Academy of Sciences of Paris, November 17, 1845, Monsieur Boussingault communicated an extract from a letter from M. Joachim Acosta, of Bogota, relative to the potato disease. It appears from this letter that the malady is very common on the table-land of Bogota—that it is destructive in wet seasons, or even every year, in damp spots. This does not prevent the tubers being used, when the affected part has been removed. It is known that potatoes are indigenous to this plain. M. Acosta does not doubt that the malady has always been known there, since it excites no alarm in the Indians, who live principally on potatoes. M. Boussingault properly remarks that, in these countries, where cultivation continues without intermission during the year, and where the tubers are consumed without the necessity of storing them, there is no fear, as with us, of a bad harvest, because it may be immediately replaced by a good one.

With us, where the culture is annual, and must be preserved through winter, it is natural that we should be more concerned in a malady which may destroy the resources of a whole year.

M. J. B.

From the Gardeners' Chronicle and Agricultural Gazette of December 13, 1845.

GREENING POTATOES.

I wish I could confirm a correspondent's experience relative to the beneficial effects of greening potatoes; but here the green ones have not kept so well as those not exposed. With me it has been a practice, for some years past, to lay such potatoes as were not fit for table out to green daily as they are dug; and this year, at the time the disease made its appearance, I had several bushels so exposed, and perfectly green. Some of these potatoes had been exposed two months, being the refuse of the frame-forced ones, and had been severed from their parent stem long before the disease was heard of; so that those who assert that it commenced in the stem or haulm will see that it seized those which were stemless at the same time. The malady first made its appearance here on some ash-leaved kidneys, planted upon the "lazy-bed" fashion; the beds, however, being filled with the refuse of the garden and pleasure ground, with sufficient hot dung to excite fermentation. This rubbish was put in in sufficient quantity to raise the beds considerably above the level of the surrounding soil; so that it was perfectly porous and dry, and the potatoes were of the finest quality imaginable. Shortly afterwards it manifested itself on two other pieces of the same kind—one a piece well drained and trenched the autumn before planting; and the other a piece of ground newly taken in, well drained, and deeply dug, but not trenched.

On the latter piece of ground every potato was rotten, and the other (about one-half) was lost; so that, although they suffered the most in untrenched ground, where the water could not pass rapidly away, perfect drainage did not stop the disease.

All these potatoes were dug on the same day, and laid out to dry and green; and though they were exposed for two months, and perfectly greened, the disease is still spreading in them. At the time these were dug, (the end of July,) a peck or so was found among them that had made young shoots, and were perfectly sound. These I immediately planted with some of Chapman's kidney, for winter use; and though the latter produced a tolerable crop of sound tubers, very few of the ash-leaved made their appearance above ground. I examined the sets to-day, and find most of them sound, and intend, as an experiment, to take them up, and replant them deeper, to see if they will produce a crop in the spring.

WM. P. AYRES.

From the Gardeners' Chronicle and Agricultural Gazette of December 6, 1845.

I am sorry to add, that I saw a self-set potato the other day, from an early kind, about three inches high, or, in fact, as early potatoes are generally in the middle of May, which had the mildew fungus precisely similar to those of September last; the leaf had the same black rings or spots, and decay had already commenced: this augurs badly for those of the spring planting. As to those planted in spring, I am much afraid that precautions will be vain, as I have no doubt the very hedges are full of the sporules of this sad mildew. The oak and the black thorn, and the common nettle, were prematurely destroyed around the potato fields in this neighborhood, at the period when the mildew was at its height; they also decayed in black patches in the leaf, as the potatoes, but whether the same, or a fungus at all, I cannot say; things looked very suspicious. The oak and the nettle were generally affected.

R. ERRINGTON.

OULTON PARK.

[We trust there is no real cause of alarm on this head. Experiments, conducted for the purpose of ascertaining whether the disease will appear in any other crops, seem, at present, to show that there is nothing to apprehend. There can, however, be no doubt that every possible means should be taken to secure a healthy growth next year.]

From the Gardeners' Chronicle and Agricultural Gazette of December 20, 1845.

REMARKS OF THE EDITOR.

These were the just views of *Mr. Garden*, of Glenae, to which we alluded last week: "We may, for a time," says this gentleman, "raise species of *diseased* plants, and employ these as seed (sets) of the next crop. Nothing can be more manifest than that the offspring of diseased parents will participate in the disease, and even be incapable of cure, or of becoming the seed of a healthful crop on any soil. * * It is evident that dis-

eased plants may be more easily cultivated on a healthful and fresh soil than on one which is diseased and run out. * * * But the *abundance* and *healthfulness* of the crop are two very different things. It is well ascertained that seed potatoes (sets) taken from the fields on the higher grounds, and where potatoes have been much seldomer cultivated, are less liable to fail than those raised on fields which have produced *many* potato crops. * * The latter, *forced* in diseased or exhausted fields, are unfit for seed (sets) in any situation."

A potato, forced in rich land, nursed in a warm valley, and unnaturally expanded into a monster of its kind by high and debilitating manure, becomes well suited to the table, but has an uncompacted tissue and a feeble constitution. A small matter makes it ill. Its unhealthiness is communicated to its successors, and so the evil is ceaselessly augmented. On the other hand, a potato raised in poor or rocky ground, small and compact, thoroughly organized by the action of healthy foliage operating upon a small surface, will not answer, indeed, the purpose of the grower of a crop, but is admirably adapted for his sets. It is not in itself marketable, but it forms the best of seed. Thus it was that the small green stem-potatoes, which high cultivation has almost driven out of recollection, always proved the best of all for sets, though utterly uneatable and useless for the table.

What we then would advise growers to do, is, not to indulge in a vain hope that seedling potatoes will be any better than what they now have; but to adopt the practice of raising potatoes for sets upon a different principle from those which are for the table; to treat the latter as they now do, but to grow the former in poor, light land, where there shall be no excessively rapid growth, and no great produce, but where a small, compact potato, thoroughly ripened, thoroughly organized, and therefore thoroughly healthy, will be a guarantee that all the freedom from disease, which, in the nature of things, is to be expected, shall be secured for the crop it is to furnish, beyond all chance of risk.

If such potatoes are left in the ground all the winter undug, or are planted in the autumn, or, if taken up, are thoroughly greened and packed in sand, and planted before sprouting, a far more rational means of renovating the potato crop will be adopted than running to Peru for seed not half so good as our own.

—

POTATO MURRAIN.

It is the belief of some that a fungus is the cause of this disease. From facts, however, which have come under my own cognizance, I am led to hold a contrary opinion. I have about three or four bushels of last year's potatoes (they have been about twelve months out of the ground) that have been since spring in a corner of a tool house, held up in front by a few loose bricks; and, as might be expected, they have put forth numbers of small tubers, and the greater part of these small tubers are diseased, and bad as any that have been grown in the soil in the open air. I should suppose that the manner in which the fungus is conceived to affect them, is by a transition from the leaf to the tuber; however, in my case, it will be perceived that such is not the case, as not a single leaf has been formed. The small tubers have been produced from the intercellular tissue, or elaborated

matter of the old potato, and without the assistance of any foliage whatsoever; but, as the tool-house door stands open all day, and the potatoes are not far from it, they are consequently under atmospheric influence, and the greater portion of them are covered with fungus, which seems to have proceeded from the top to the bottom of the heap. I have, likewise, some early potatoes that are diseased to the very centre, without a fungus having yet made its appearance upon them. These two facts surely prove that the fungus is not the primary cause of the disease, which certainly does not occur through the agency of the leaf. I have always been of the opinion that it is to the dull weather we have experienced that we must attribute the cause. The plants have been charged to excess with water, which, owing to the absence of sunlight, could not pass off by evaporation; this, then, has produced a disorganization of the tissues, and disease has followed in consequence.

I observe an article in last week's number setting forth the average quantity of rain that has fallen during the last eight years, as a proof that the disease is not caused by moisture. It is not the great quantity of rain that has fallen that is to be considered the cause, for we certainly have had more in other years, but the absence of bright sunlight must be kept in view; for days the sun never broke forth to dispel the moisture of the atmosphere, or to elaborate the juices of the plant. I cannot conceive any other cause for the small tubers grown in the tool-house being diseased, unless it is to be ascribed to some unknown atmospheric condition. This fact sets at rest the opinion as to manure of any kind being the cause, none whatever being present. Lime cannot be considered an antidote to the growth of fungus; for a great quantity of diseased potatoes here has been well dosed some time ago with caustic lime, and on many of them the fungus is abundant; not even drying and greening by exposure will entirely prevent its growth, as I myself have proved, although it does partially. Mr. Ayres remarks that he cannot add his testimony to the beneficial effects of greening. If the potatoes are diseased previously to greening, the disease will proceed, although much more slowly; and such, I have no doubt, was Mr. Ayres's case. Such is the case with some of mine; but greening potatoes for seed, if perfectly sound, I believe does produce beneficial effects. That the potatoes have received the disease during their growth, I feel firmly convinced; otherwise they would not receive it after, for I have some ash-leaved kidneys green, and ripened early on a raised slope in the garden, and greened by a long exposure, and they are now as promising seed as I could wish, and I have no fear that they would have remained sound if not greened. The question for seed another year appears to me a serious one. I am afraid planting potatoes diseased at all, either now or in the spring, will prove a fruitless effort, as I doubt not they will rot when they come in contact with the moisture of the soil.

HENRY WOOD.

From the Manchester Guardian.

THE POTATO DISEASE.

At a meeting of the Manchester Literary and Philosophical Society, Mr. A. Campbell, curator of the botanic gardens, stated that he had tested the

efficacy of fumigating with sulphur, suggested by Mr. Thorn, and had found that in those potatoes which had been subjected to the process the disease never made any further progress, even though they were subsequently placed in contact with diseased tubers. He also referred to other experiments, most of which went to prove the necessity of exposing the potatoes to light and air, and the evil effects of hogging or pitting them. Mr. Dale said he had planted a potato which had been fumigated, and found it to vegetate as well as those to which sulphur had not been applied. The whole of the observations that were made confirmed the accounts previously given, and light and air, a good ventilation, and a frequent examining and turning of the potatoes, are the most effective agents in checking the disease.

From the Mark Lane Express, December 1, 1845.

POTATO DISEASE.

From the Leicestershire Agricultural Report.

So much has been said and written upon this matter, by the learned and the unlearned, it would be presumptuous in us to make any lengthened remark as to what means should be taken to arrest the malady; but, as it is generally admitted that it proceeds from an excess of water in the tuber, we believe the best way to preserve them is to cut every potato in two, or if small, a considerable piece off them, which gives vent to the watery matter; and if they are stored in chaff, slacked lime, or anything of a drying nature, they are likely to escape the decay which otherwise awaits them. Even the saving of some for seed becomes a matter of great importance. There is no fear as to the diseased tubers growing, as a friend of ours stated he had seen sets with shoots more than an inch long from diseased potatoes, which lay in a warm place. We believe that, in this country, not one sixth the usual quantity will be preserved until the spring.

From the Berkshire Agricultural Report.

We know not whether the distemper, that certainly has prevailed with more or less violence, is likely to be reproduced by the tubers hereafter to be planted; but it cannot be doubted that the tainted ones are wonderfully excitable. The eyes, if they do not push shoots, are inclined to produce a perfect young tuber; and therefore a full experiment ought to be tried at once, by sowing extensively such potatoes as are sound within, though affected superficially—taking care to cover each row with atl east twelve inches of good earth. Another method of planting migot oe, o make drills, six inches deep and two feet asunder, covering first with earth, and then with as much coal ashes. These could be raked off in spring, and scattered over grass or clover land, to which latter they are applicable,, specially when they contain gypsum, of which we have detected, occasionally, nearly ten per cent. Another fact is worthy of mention. Though no one can doubt the attack of the haulm as the early indicator of disease, in

the *first period* of its attack, about August, yet the condition of the leaf in October and November was no certain index. Two plots of potatoes, standing side by side in one field, each about forty yards long, ten yards wide, exhibited appearances totally different. One, the Jersey blues, had no sign of vegetable life remaining early in October; its neighbor, a white variety, was verdant as spring. Suddenly, the latter became affected at the close of October, and both were dug up about the 10th November instant.

The *blues*—those which were black six weeks before the others gave any sign of disease—*were nearly all sound.* Of the whites, 150 bushels were raised, and only 18 remained fit for pigs!

From the Mark Lane Express, December 1, 1845.

POTATO DISEASE.

To the Editor of the Salisbury and Winchester Journal:

Sir: It is now some years since, after a severe winter, and the snow lying long on the potato pits, I found, on opening them, a very considerable portion apparently completely destroyed by the frost. My bailiff was about taking them to the dung-heap; but, with no trifling difficulty, I induced him to fill our steaming tubs, and, to my delight and astonishment, we found, after the operation, their contents as fair, and the meal as fine, as from the potatoes that were perfect.

It is now about three years since that I discovered a pit containing about a hundred sacks of potatoes, showing a sinking upon the surface, which induced me to suspect mischief. I directed them to be opened; and the effluvium arising from them was frightful. We found nine-tenths of them more or less affected. I would not, however, throw them away without trying the effect of steam; when again, to my surprise, the offensive matter was removed, and the remainder was perfect and fit for use. I scarce need say that I am pursuing the same operation with the diseased potatoes of the present year, and have great pleasure in stating, with the most perfect success. I have grown between seven and eight hundred sacks, of which I consider nearly one fourth to be more or less affected; but all fit for the steamer.

When thoroughly steamed, and not required for immediate use, it would be desirable to place them in a tub or vat, (but sunk in the ground to keep them air tight,) and thoroughly beaten with wooden rammers. A little salt sprinkled over them during this latter operation will keep them sweet and fit for use for many months to come.

J. PENISTON.

RENOVATION OF THE POTATO BY SEED.

Having three times, during a long life, raised potatoes from the seed, and minutely observed the progress of vegetation from the period of sowing to

the maturity of the crop, and having given my best attention to the culture in every stage, my practical experience and observations convince me that the time has now arrived which makes it imperative to renovate the *potato by seed.* The first step in this experiment is to collect the balls, or seed berries, or potato apples, as they are called, and place them in a dry situation; but these would have been found with greater facility before the late crop was raised; yet there are a sufficient number to be found scattered about the land where they grew, on every farm. The apples, having been hoarded till as mellow as ripe plums, must be squeezed by hand in a basin of water, till the tough skin and pulp are well separated from the seed, the latter of which will readily quit the former, and precipitate to the bottom of the basin; the water must be poured off and the seed spread thinly on a coarse cloth to drain and absorb the remainder of the water; and then removed and spread upon brown paper, and, when perfectly dry, must be well preserved till the following spring, for sowing.

I have found the most favorable time for depositing the seed in the ground, well pulverized, is the second week in May, or thereabouts; at this late period the probable occurrence of frosty nights may be less prevalent than at an earlier sowing, as the tender plants springing up are extremely susceptible of the least frost. The operation of sowing may be performed precisely the same as with onion seed, and there will be no particular care to be further taken before the time of transplantation.

The seed will come up freely, and the plants, when elongated three or four inches, should be carefully raised with as much root as possible adhering, and removed into small trenches ready to receive them, and planted to the depth of the under leaves, distant about six inches apart in the trench, the trenches being about fifteen asunder; and the earthing up may be performed in the usual way as the plants progress; but the transplanting operation will be more favorably done should the earth then possess natural moisture. As the plants advance towards maturity, some will exhibit great luxuriance a long time, and others will sooner appear to droop; the latter indicate an earlier sort, and may be distinguished by placing a little stick at the haulm. The process now terminates; but the fruits of the labor in raising the ripe crop will present a scene to the operator truly wonderful and amusing; he will behold amongst the vast variety of new potatoes, at the roots, from the size of a pea to that of a pullet's egg, purples, whites, flats, rounds, kidneys, &c.—in fact, such demonstrations of the sports, freaks, and vagaries of nature, as are truly astonishing. These new roots must be planted whole the following season; and after, they will be in perfection for selection as future stock.

SENEX.

GLOUCESTER, *November* 19.

From the Mark Lane Express, Dec. 8, 1845.

To the Editor of the Dublin Evening Post:

DEAR SIR: The disease of the potato, I believe, arises from an excess of moisture in the tuber. It is not surprising that potatoes surcharged with moisture should heat and decay when deposited in close pits. Grain put prematurely together would likewise decay. With respect to diseased

potatoes, I have to observe, that I cut some of them with a view to ascertain whether the disease would go forward in the sound when removed from the diseased part. More than three weeks have elapsed, and the disease has not made further progress in the diseased portion, whilst the sound continues sound. The superfluous moisture appears to have escaped by the incision, and the disease to have been arrested in its progress. It appears to me that the redundant fluids of the potato press towards the outer rim, and not finding a vent, the disease commences like a bruise, round the rim, or in the weakest part of the potato. Cut the potato across, and, as far as I have observed, the disease is arrested, when the operation is timely performed.

I dwell on this, because I fear a considerable portion of the crop will, from time to time, become diseased, and because I conceive the cutting of the potato will save the greatest part, at least for present use, as human food ; and I think it, moreover, probable, that in many instances it will be found expedient, as a measure of precaution, to cut a portion from the sound potatoes for seed or other purposes, and thus relieve them from their superfluous moisture.

With respect to a future crop, I would strongly recommend that all small potatoes should be reserved for seed. It has been generally remarked they are this year the soundest; and this, probably, arises from there not being such a body of superfluous fluid in them as in the large. I have proved, by experiments, the great value of small potatoes planted entire. They should be closer set than the large ones; and, if properly attended to, a full crop may be expected.

I perceive by the public papers that a learned German professor, and others, expect relief next year from the seed of the apple, to be sown in the spring. It is certainly most desirable that the raising new kinds from seed should be generally adopted; but, as far as my experience goes, it is some years before new kinds are fit for human food, and the proportion of those which prove eventually good is very small. In consequence of the partial failure of the potato crop in 1831, I sowed the seed of the white apple and pink-eyed species in 1832, in the same manner as celery. The young plants are very delicate. They should be transplanted when sufficiently strong, in drills. A perch of ground produced 102 pounds, and exhibited a great variety of kinds. Each kind had its trial for one or more years; and such as were considered incapable of improvement were rejected. Ultimately, two kinds only were considered worthy of cultivation ; and I send you specimens of one of them, which I call the Palmerston apple-cap, from having been cultivated there. You will perceive that it is an excellent potato. I have more than 30 tons of this kind—most valuable for seed. The disease in this species was by no means so bad, nor to one-tenth of the extent that pervaded apple potatoes of the old kind, which adjoined them in the field. Their constitution being more vigorous, resisted the disease ; but there was disease amongst them, and the same superabundance of moisture that may generally be perceived in potatoes this year.

Yours, faithfully,

LELAND CROSSTHWAIT.

From the same.

Dear Sir: An industrious person, for whom I entertain a regard, and whose crop of potatoes consisted of about three tons, of excellent quality, obtained leave to place them on a spacious air-drying loft, which afforded an opportunity of spreading them thin. After the lapse of a few days they lost their bright color, and were discovered to be so seriously affected, particularly the largest and finest, that they were of little value. I prevented him from throwing away a quantity of them. They have since been cut across, and the progress of further decay has been arrested; and the color, in a great measure, restored. Those which were accidentally cut with the spade almost entirely escaped; and also the small ones, with little exception. They will all be reserved, and will, I doubt not, make excellent seed.

As to the large potatoes, the keen air to which they were exposed checked evaporation, contracted the outer coat, thereby causing a pressure on the potatoes in a state of plethora, as they mostly are this year, and producing the bruised appearance, which has been considered a particular disease of so insidious a character as to render potatoes so affected unfit even for pigs.

I find, in an article from Lower Saxony, November 6, that amongst the methods adopted to stay the malady, which had accelerated and increased its ravages, was that of large cultivators having exposed the dug-out bulbs to a current of air.

It thus appears that the same cause in places so far asunder has produced the same effect, and it may probably be inferred that the disease is the same. It has been by many considered that the disease proceeded from the leaves and stem to the root; but some potatoes are affected at the butt, whilst the crown is quite sound. Others suppose that the disease proceeds from fungus; but, as far as I have observed, when this does appear, it is not until a potato has reached an extreme state of decay, and it seems to be the consequence rather than the cause of the disease; besides, fungi are occasionally discovered every year in decayed potatoes.

Greatly alarmed a month back, I intended that all the stalks should be burnt, in order to prevent the supposed infection from spreading; but close observation has altogether changed my opinion, and they have been added to the dung-hill. It has also been said that late potatoes were the most subject to the infection; but nearly one-half of the old apple-potatoes, to which I referred in a former letter, and which were planted in March, were diseased; while, in three-fourths of an acre of "Palmerston apple-cap potatoes," planted 3d July, after a crop of rye used for green feeding, only $\frac{1}{75}$th part has hitherto proved to be affected; but, on the other hand, potatoes planted before the severe frost of last winter escaped entirely. I mention the latter circumstance, lest an opinion might otherwise be considered as having been given in favor of late planting, which ought to be avoided, except under particular circumstances.

In order to ascertain whether the disease could communicate any injury by being put in contact with the sound part of a potato, I cut diseased potatoes across, which were sound in the centre, made excavations in them, put pieces of highly injured potatoes to fit therein, and then tied the cut pieces closely together. On opening them after some days, I found that the disease had not been communicated to the sound parts, but that the diseased parts had materially improved. My friend Sir James Murrey, who had read my letters to you, informed me on Friday last, that, amongst other experiments,

he cut off the sound part of a potato from the diseased, and applied a preparation of lime to it. The result was, that the application deteriorated the sound part, whilst the mere incision, without any application, improved the diseased part.

LELAND CROSSTHWAIT.

From the Mark Lane Express and Agricultural Journal, of Dec. 15, 1845.

MAJOR BEAMISH'S EXPERIMENT.

We are authorized to state that the simple method of rendering diseased potatoes available for human food by boiling them in two waters, (the first being thrown away when it has reached the boiling point,) has been tried by Major Beamish with complete success. He purchased, we are informed, last week, 100 weights of so called diseased potatoes, at the current depreciated rate of twopence per weight, for the purpose of giving them to cattle, (conceiving, with the seller, that they were fitted for no other purpose,) and had already applied many of them to that use; but after seeing a statement in the public prints, he had a portion taken indiscriminately from the heap and boiled according to the prescribed directions. The result was in every respect corroborative of the first experiment. The whole of the black acrid matter, which in few cases extended beyond the skin, was completely extracted by the first water, and the potatoes, when served up to table, after the second boiling, presented as sound an'appearance and were as dry and palatable as any potatoes of the kind, under the most favorable circumstances. They were the common white lumper or horse potato, and were cooked "in their jackets."

From the Mark Lane Express and Agricultural Journal, of Dec. 22, 1845.

THE POTATO DISEASE.

The assertion of a fact seems to me to offer a clue to this great enigma, which has afforded so much excitement. It is the presence of sulphureted hydrogen in rain water in and during the latter end of summer. This I observed, and proved by chemical means; indeed, the water was so much impregnated with it that the presence of lead turned it to a deep brown. This fact, I find, does not only rest upon my own observation, but acute observers, who have no pretension to science whatever, have noticed this peculiar state of rain water at times, and even at miles distant. Now this cannot be a mere local case, for there is no local cause. It must be more universal than in the immediate neighborhood, as there is nothing to afford the slightest cause for its being generated; and though it is sometimes given out in vegetable decay, as in pools, &c., yet it made its appearance at a time when Britain's verdure was at its height.

Thus, there does not appear any probable cause for so remarkable a phenomenon in England; so, consequently, we must look for a cause beyond the sea. The remarkable exhalations of some of the European volcanoes, which have been reported, seem to afford a probable cause for its existence,—as the property of this gas on mixing with water is well known.

Now, having seen that such did exist in rain-water, and that, in all probability, it originated with some volcanic eruption, let us see the likelihood of its being the cause of potato decay. It is reported that it is not known in the more southern countries; this is what one might expect from such a cause, and to suggest a theory of its probable manner of acting. Its power of deoxydizing metallic oxides in solution is well known to chemists. Now, according to Sprengel's analysis, potatoes contain, of their weight, about $\frac{1}{30000}$th part of oxide of iron. The impregnated water acting upon potatoes in deoxydizing the iron, might produce, to all appearance, little effect at the moment; yet, in process of time, the iron would begin to attract oxygen again, when hydrogen would be liberated, and, by the vis-inertia, combine with the nitrogen, and produce a decay in the potato.

Such a theory appears probable, though it may not be quite correct; but at all events, I have, by artificial means, produced similar results. I took a few small round potatoes—the best I could pick—and steeped them in strong impregnated water two or three days. I then poured off the water, when they appeared no different. In the course of two or three days or so, I found some of them covered with a white mould, and all beginning to feel rather soft; and about the fourth night, all going more or less—some presenting nearly throughout a gray appearance, much after the manner of those I have examined that have gone of themselves; and, indeed, a practical farmer told me they quite resembled some of his; and I also found a considerable quantity of starch, to all appearance no worse, which I extracted out of the worst part. This experiment goes to prove the preceding views. It is also reported they all went not in the tubers, but in the stalk. Now, the water soaking into the stalk would show itself there first; but the impregnated water, in passing through the soil, would become partly decomposed, though not quite so; consequently, it seems to harmonize with the account.

It has also been stated that Mr. Rees's suggestion of chlorine has also restored them. Now chlorine, as well as its antiseptic properties, decomposes sulphureted hydrogen. Thus, all reports serve to corroborate the truth of what has been stated, and much more might be stated in its favor; but, after seeing that the presence of a gas in rain water—a produce of volcanic eruption at a time when such were pouring out most furiously, and when there was no other probable cause—it makes it almost indisputable that such was the origin of it; and having shown that this was capable of producing dire effects upon potatoes, these, together with other corroborations, place it almost without doubt, wanting nothing but a philosophic history of the disease, together with the state of the winds, to make it as clear as if Euclid had demonstrated it.

Broughton in Furness, *December* 6, 1845.

From the same.

DISEASED POTATOES.

Our attention has been called to a circumstance which may be of service to those who are employed at the potato mills, among the diseased potatoes. Two men belonging to the town, employed some weeks ago among the potatoes preparing for the new mill at Friartown, happened to get (one a thumb and the other a finger) slightly scratched; but so trifling were the

wounds that they paid no attention to them, and continued at their work two or three days after. The injuries, however, continuing to increase in severity, the limbs having become dreadfully swollen and painful, they were obliged to drop work. The swelling, accompanied with the most severe inflammation, continued to increase, extending along the hand and up the arm; and to such a state has it reached that at the present time it is doubtful whether both the workmen may not require amputation of their arms to be performed. A boy, about eight years of age, while engaged in grating diseased potatoes, about five weeks ago, to make weavers' dressing, got a finger scratched upon the grater, and is also in a state of suffering similar to that stated. This leads to the belief that there must be some highly poisonous quality in the potatoes, of which it would be well for those who work among them with broken skin to beware.

From the Gardeners' Chronicle and Agricultural Gazette, November 1, 1845.

REPORT OF IRISH COMMISSIONERS.

The commissioners in Ireland, directed to inquire into the disease which has attacked the potato crop in the United Kingdom, consist of Professors Kane, Playfair, and Lindley. Their first report, directed merely towards the prevention of improper methods of storing the crop, has been published by the Irish government, and distributed, by means of the constabulary, through the whole country. We reprint it, and shall continue to give our readers the succeeding reports as soon as they have been made public. As they will contain all that is considered worth recording respecting this fatal disease, it will be needless henceforward to occupy much space with other comments.

As we said before, the issuing of this commission is a sufficient proof of the prevalence of the potato murrain to a most formidable extent, and of the accuracy of the view we have always taken of its importance.

We by no means blame those who, disbelieving the extent of the mischief that has been done to this crop, charged us with exciting undue alarm. They had not our means of gaining information. We hope, however, that on a future occasion, when we shall again have to anticipate the ordinary intelligence of newspapers, if such an occasion should unhappily arise, those who disbelieved us in the present instance will give us credit for not making assertions without due authority.

In Ireland the official inquiry is essentially aided by the important evidence collected by various diligent inquirers, especially by the *Royal Irish Agricultural Improvement Society*, a most zealous and useful association, and the officers of the *Royal Dublin Society*. In England the Rev. M. J. Berkley and Mr. Edward Solly are occupied with a minute investigation of the subject for the *Horticultural Society*, in the mycological and chemical points of view; and in Scotland the *Agricultural Chemistry Association* have put forth a circular inviting the public to subscribe five hundred pounds! for the expense of an entomologico-botanico-chemico-practical examination of the subject.

The following is the report above alluded to:

"BOARD-ROOM, ROYAL DUBLIN SOCIETY,
"*October* 24, 1845.

"MY LORD: We, the undersigned, commissioners appointed by her Majesty's government to report to your excellency on the state of disease

in the potato crop, and on the means of its prevention, have the honor to inform your excellency that we are pursuing our inquiries with unremitting attention.

"We are fully sensible of the important and difficult nature of the inquiry, and therefore are unwilling to offer, at the present moment, any final recommendations, as we are still receiving evidence, and awaiting the results of various experiments now in progress. But at the same time, we ought to state to your excellency that we have reason to hope that the progress of the disease may be retarded by the application of simple means, which, we trust, may appear worthy of adoption, until we are enabled to offer further recommendations.

"In the present communication we avoid entering into any account of the origin or nature of the disease; but we would particularly direct attention to the ascertained facts, that moisture hastens its progress, and that it is capable of being communicated to healthy potatoes when they are in contact with such as are already tainted. A knowledge of these facts, determined as they have been by experiment, and agreeing with the scientific information obtained as to the causes and nature of the disease, leads us to propose the adoption of the following plan for diminishing the evils arising from the destructive malady:

"In the event of a continuance of dry weather, and in soils tolerably dry, we recommend that the potatoes should be allowed for the present to remain in the land; but if wet weather intervene, or if the soil be naturally wet, we consider that they should be removed from the ground without delay.

"When the potatoes are dug out of the ground, we are decidedly of opinion that they should not be pitted in the usual way, as the circumstances under which potatoes are placed in ordinary pits are precisely those which tend to hasten their decay.

"We recommend that potatoes, when dug, should be spread over the field, and not collected into heaps; and if the weather continue dry and free from frost, that they should be allowed to lie upon the field for a period of time not exceeding three days.

"The potatoes, after being thus dried and improved in their power of resisting disease, by the means proposed, should then be sorted by carefully separating those which show any tendency to decay. Those potatoes which appear to be sound should then be placed about two inches apart in a layer, and over each layer of potatoes should be placed a layer of turf-ashes, or dry turf-mould, or dry sand, or burnt clay, to the depth of a few inches. Thus will be formed a bed of potatoes, each potato being completely separated from the other by a dry, absorptive material; upon this bed another layer of potatoes should be spread in like manner, and also be covered with the dry materials employed. As many as four layers may thus be placed one above the other; and when the heap is completed, it should be covered with dry clay, straw, heath, or any other material adapted to protect it from rain.

"In the event of the weather becoming wet, these recommendations are not applicable. In that case, we would advise the potatoes to be packed in small heaps, with either straw or heath interposed, and well covered; in such a situation they should become as well dried as seems practicable under the circumstances. When out-buildings exist, it would be advisable that this mode of temporary packing should be carried on in those places. If there be no outhouses, the heaps may be left in the open field. We,

however, particularly recommend that potatoes should not be removed into inhabited rooms.

"With regard to the treatment of potatoes already attacked with the disease, we have to state that in this early stage of our investigation, we do not feel justified in proposing to your excellency any mode of positive treatment: this subject we reserve for a future report; but we may remark that exposure to light and dryness in all cases retards the progress of alterations such as the disease in question, and we therefore suggest that all such potatoes should, as far as possible, be so treated.

"We do not mean to represent that these recommendations, if carried into effect, will prevent the occurrence of disease in potatoes; but we feel assured that the decay will extend less rapidly and less extensively under these circumstances, than if the potatoes, when taken from the ground be at once pitted in the usual manner. Neither do we offer these suggestions to your excellency as a final means of securing the crop, but merely as a method of retarding the progress of an enemy whose history and habits are yet but imperfectly known, whilst we endeavor to ascertain the means of more completely counteracting its injurious effects, if any such can be discovered.

"All which we submit to your excellency's consideration, and remain, your excellency's obedient and faithful servants,

"ROBERT KANE,
"JOHN LINDLEY,
"LYON PLAYFAIR.

"To His Excellency Baron Heytesbury, &c.'

From the Gardeners' Chronicle and Agricultural Gazette, Nov. 8, 1845.

SECOND REPORT OF IRISH COMMISSIONERS.

Board-room, Royal Dublin Society,
October 29, 1845.

My Lord: Having submitted to your excellency, in a former report, some preliminary instructions intended to prevent improper treatment of the potato crop still remaining unaffected, we now have the honor to lay before your excellency our views regarding some processes of treatment for the potato, which appear to us to be of practical value and importance.

We are deeply sensible of the incompleteness of form which this mode of presenting our results to your excellency necessarily assumes, but the exigencies of the case are such, that we consider it our highest duty to bring at once under the notice of her Majesty's government such principles, or modes of practice, as, upon due consideration, we feel authorized to recommend.

We have been engaged in the investigation of many plans for preserving diseased potatoes, as proposed by other persons, or suggested by ourselves, and we have been collecting precise information as to the experience of others in their endeavors to arrest the progress of the disease. From all the results that we have obtained, we feel justified in submitting to your excellency the following observations:

Plans of treatment have been proposed by persons possessing more or less chemical knowledge, in which, by some, acids are to be employed; in others, alkaline liquors; and in a third class, gases, such as chlorine.

These processes we dismiss from further consideration, as, even did they in the laboratory answer the intended purpose, they are totally inapplicable to the circumstances of the produce of an entire county, and to a population such as that for whose welfare your excellency is so deeply anxious. Other methods, apparently more practical, consist in the treatment of the potatoes with chloride of lime (bleaching powder) and salt, either separate or in mixture.

The result of our own experiments, and the evidence we have received concerning trials made by persons in whom we have full confidence, authorize us at once to recommend the rejection of those materials. We have found the decomposition of the potato decidedly accelerated by their application. With respect to lime, the results of our own experiments are not yet decisive; nor is the experience of others as yet satisfactory. We therefore reserve this point for further consideration.

Whilst the disease is not yet very far advanced in the potato, it is certain that, after being boiled or steamed, it may be employed as food for immediate use, both for man and other animals, without prejudice to health.

When the disease is more advanced, so as to have invaded a large part of the potato, and when the tubers have acquired a disagreeable smell, their influence on the system is more questionable.

We have put in operation a series of experiments in order to determine this point, and will, in due time, report the result to your excellency. As, however, the potato, when once affected, quickly runs into total decomposition if left to itself, it is evident that its consumption merely for the purpose of food cannot be sufficiently rapid; and it therefore becomes necessary to consider to what other uses it may be applied.

The extraction of starch from potatoes, and its use as food, having strongly attracted public attention, and conflicting and in many cases inaccurate opinions having been entertained on this subject, we consider it of paramount importance at once to direct your excellency's attention to the actual state of knowledge regarding this material.

It is recognised that the potato, in relation either to its weight or bulk, is one of the most inferior articles of food. In its ordinary state of sound constitution, every hundred pounds by weight of potatoes contain, on an average, 74 pounds of water, of skin and fibrous matter 8 pounds, and of starch 16 pounds; whilst of gluten, the most nutritious of vegetable matters, and which predominates in corn, there is not more than 2 pounds in the above quantity. It is quite certain that starch, or materials corresponding to it, exist to a certain amount in every variety of useful food; but it is equally certain that in food, starch is not the material which serves for the support of the animal frame; and an animal fed on starch dies of starvation nearly if not quite so soon as if totally deprived of food. Hence starch, extracted from the potato, cannot be viewed as a substitute for the potato itself; and we consider it of great importance that while the attention of the people is directed to the real value of starch, and the uses to which it may be advantageously applied, they should not be allowed to rest their hopes of nourishment during the succeeding season upon any store of it alone.

With this preliminary caution, we have to state to your excellency that

probably the best use to which diseased potatoes may be applied is the extraction of starch. In a commercial point of view, the starch represents a considerable proportion of the value of the potato, although it is not at present in as large a quantity in the unsound tubers as in those which are free from disease. The extraction is simple, and consists in processes which we need not here describe, as they are given in the current publications of the day, and indeed are already practised in most parts of the country.

Your excellency is aware that we are directing our attention to the manner in which starch can be advantageously employed. It can be worked off, and with utility, as food, when mixed with proportions of oatmeal, bean-meal, or peasmeal; and such intermixture forms an excellent and economical article of food. It is also to be remarked that the pulp remaining after the extraction of the starch from the diseased potatoes contains a considerable quantity of nutritive material; and as the decomposing substance is, to a very great extent, washed out during the preparation, the pulp may, when dried, be applied with confidence to the nourishment of animals. Further, if the dried starch extracted from the potato be mixed up with the dry residual pulp, a material will be produced really representing the potato, equivalent to it as food, and, if kept dry, capable of being preserved for a considerable length of time. It of course must be prepared for use by cooking or baking in the ordinary way.

The manufacture of the pulp and starch on an extensive scale, in accordance with these suggestions, we venture to consider worthy of your excellency's attention. It is an operation not suited to the circumstances of isolated cotters, and just now might not be a proper object for commercial speculation.

But arrangements might possibly be made for carrying out this recommendation through the agency of the poor-laws unions, and other government establishments, in which mechanical power and intelligent superintendence could be speedily and economically applied. We feel, however, that even these facilities for the conversion of the tubers may not be sufficient to keep pace with the progressive injury which, it is to be feared, the potato crop is sustaining.

We therefore recommend a mode by which we believe the process of decomposition may be retarded. In our preliminary report we mentioned to your excellency the important influence exercised upon the disease by moisture and dryness. Our subsequent investigations have confirmed this opinion; and we believe, where means exist for a more complete drying of the tubers, such a method will prove the most efficacious plan for preserving the potato from further decay. This more perfect drying cannot, however, be effected in this climate by mere exposure to air. It requires artificial heat, applied in some form of kiln; and without entering into mechanical details, we may name some contrivances which seem well adapted to the purpose.

The corn kilns, extensively distributed through the country, may at once be applied to the drying of potatoes; which will, however, demand a temperature rendered gradually higher than that required for corn. But as in many cases those kilns are at present fully occupied, we would represent that every lime-kiln may be adapted to the purpose without interfering with its ordinary operations, by erecting over it, at a suitable height above its mouth, a framework of hurdles, upon which the potatoes may be spread in a thin layer, fresh potatoes being added as the others become dry and are

removed. In localities where the previous means do not exist, or may not be on a sufficiently extensive scale, potatoes may be spread on a framework of hurdles, supported on a few props of stone two or three feet high; one or two turf fires burning slowly under the hurdles would effect the same object. There need be no fear of the potatoes becoming slightly browned, as they are not injured thereby for future use; and the turf smoke would act favorably on the potatoes rather than otherwise. In all these modes of drying, the potatoes should be cut into two, or, if very large, three pieces, so as to allow the water to escape.

Potatoes dried in any of the modes above described are certainly capable of being preserved, when kept in a dry place and stored with the precautions described in our first report, until suitable opportunities arise for converting them into starch or meal, according to the degree in which they were affected by the disease.

It is gratifying to us to find that our own opinion as to the advantage of thoroughly drying the potato in the manner we have recommended, and by processes such as those above described, are confirmed by the experience of highly intelligent persons, who have simultaneously directed their attention to the subject.

We shall not hesitate to bring under the notice of your excellency our further conclusions; and we have the honor to be your excellency's obedient and faithful servants,

ROBT. KANE,
JOHN LINDLEY,
LYON PLAYFAIR.

To His Excellency Baron Heytesbury, *&c.*

From this it will be seen that we were right in refusing assent to the recommendations that have been offered, by various persons, of nostrums for saving the decaying crop. Even chloride of lime, positive as were the assertions of its efficacy, is condemned, and, as we now know, with perfect justice.

The first report has been made the subject of criticism by gentlemen who seem to have been disappointed at not finding effectual remedies proposed in a report whose whole objects were, as it declared, entirely temporary.

The *gist* of the commissioners' recommendations was to secure dryness, and absence of contact, by all possible means; and any intelligent man would see that the particular methods proposed were merely in reference to those all-important precautions, and might, keeping them in view, be departed from according to circumstances.

Dr. Halpin, of Cavan, has strongly urged upon the Irish potato-growers the construction of pits, in which it is supposed by him that effectual ventilation is secured by laying the potatoes on rough sticks or other materials, and introducing into the heaps cone-shaped funnels of wicker-work, the whole, except the mouths of the funnels and a hole at each end, being covered down with clay or earth. We add the reply of the commissioners to this proposition:

Board-room of Royal Dublin Society,
October 30.

My Lord: We have the honor to acknowledge the receipt of your excellency's communication of this date, enclosing a copy of a letter publish-

ed in the *Dublin Evening Mail* of the 29th, in which Dr. Halpin, of Cavan, has proposed a plan for preserving the potato crop which he considers more worthy of public confidence than that which we had the honor to submit to your excellency.

It will be observed that the author of the letter under consideration does not state that he himself has tried the method which he proposes, or derived a knowledge of its advantages from the experience others. He merely thinks that it would prove efficacious.

We can, however, state to your excellency that a plan founded on the same principle, and at least as well adapted to practice, has previously been proposed in England, and experimentally tested by one of us. The result convinces us of its total inefficiency; and the cause of failure becomes manifest on considering the manner in which the disease is propagated, and the circumstances under which potatoes are placed in ventilating pits. In such places, potatoes being in contact are precisely in the condition best suited for the extension of disease, and against the danger of which we so strongly warned the public in our first report. Further, without giving any positive opinion whether the fungi found in decaying potatoes be the cause or the effect of the disease, it is quite certain that their presence aids very materially its rapid advance, and that their transmission from one tuber to another is one of the most ordinary means of infecting those potatoes which are at all predisposed to decay. Hence the isolation of each tuber is indispensable to its preservation, and hence our urgent recommendation to interpose some dry, solid substance between each potato.

If, as Dr. Halpin supposes, gentle currents of air did occur among potatoes collected in heaps in ventilating pits, then, in that case, the germs or seed of parasitical fungi, together with the emanations from any one decaying point, would be rapidly distributed over the entire mass of potatoes. We have to state, as our decided opinion, that in such a pit no current of air sufficient to dry the potatoes in the manner anticipated by Dr. Halpin could exist; or if it were produced, could only arise from inequalities of temperature, caused by the decomposition of the potatoes themselves.

We observe that Dr. Halpin has, in some points, mistaken the object of our report, more especially in supposing that the methods of storing which we have recommended are intended to be permanent. As yet, we have given no opinion on this matter, which involves such important considerations that we must delay our suggestions on the point until some further information has been obtained.

In the execution of the responsible duty intrusted to us by her Majesty's government, we have refrained from bringing forward any theoretical or speculative opinions, however plausible. Our former recommendations were founded on the results of experience, and we continue to recommend them with confidence. We have the honor to be your excellency's obedient and faithful servants,

ROBERT KANE,
JOHN LINDLEY,
LYON PLAYFAIR.

To Baron Heytesbury, *Lord Lieutenant of Ireland, &c.*

IRELAND—THE GOVERNMENT COMMISSION.

The following is the third report of the government commissioners:

" *To His Excellency Baron Heytesbury, Lord Lieutenant of Ireland, &c.:*

"My Lord: We have had the honor to lay before your excellency reports on the diseases in the potato crop, which have been distributed extensively throughout the country. Representations, however, have been made to us that the recommendations being in the form of reports, are not likely to be of that use which the more simple form of instructions might enable them to be. We have therefore thought it advisable to prepare the accompanying directions, in the hope that the methods recommended may be easily understood and promptly carried into execution.

" We shall immediately lay before your excellency our views upon the course which should be pursued with regard to seed for a future year.

" We have the honor to be your faithful and obedient servants,

"ROBERT KANE,
"JOHN LINDLEY,
"LYON PLAYFAIR.

" *Advice, concerning the potato crop, to the farmers and to the peasantry of Ireland.*

"The dreadful disease that has attacked your potatoes is one the effects of which you can only stop by strict attention to the advice of those interested in your welfare. Many plans have been proposed, and after examining them all, we recommend the following directions:

" All competent persons are of opinion that the first thing to bear in mind are the following directions:

" 1. Dig your potatoes in dry weather if you can; and if you cannot, get them dry somehow as fast as you can.

"2. Keep them dry and cool.

"3. Keep the bad potatoes separate from the good.

" 4. Do not pit your potatoes, as you have been accustomed to do in former years.

" 5. Recollect that if they get damp, nothing can make them keep; and do not consider them dry unless the mould which sticks to them is like dust.

" Do not take them into your houses unless you want them for immediate use.

" *Digging and drying.*—As you dig the potatoes, leave them in the sun all day; and if you can, throw them upon straw, turning them over two or three times. At night you may gather them together and cover them with straw, so as to keep off frost. Next day take off the straw, spread them out, and give them the sun again. Do this for three days running if the weather permit. If you put straw enough upon them at night they will not suffer.

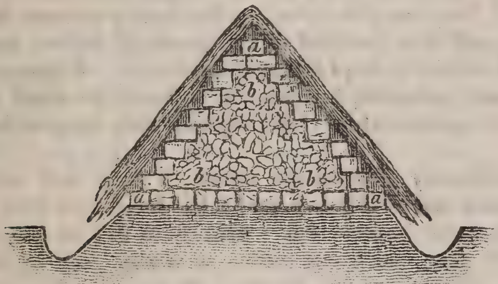
"If the weather be unfavorable, and you have a dry loft or out-house large enough to hold them, you may spread them thinly on the floor, allowing a free circulation of air so as to dry them there.

" They must be got dry.

"*Sorting the potatoes.*—As soon as they are dry you must sort them. Pick them one by one, and put in one heap the very bad ones; in another, those which are not so bad; and in a third, those that are sound. Treat

the bad potatoes as shall afterwards be directed, and store the sound ones according to the directions given in the next paragraph. You will know the very bad potatoes by their unpleasant smell, and the second set by their skin looking brown or dull, and not bright, as it generally does. A very little practice will teach you how to distinguish them easily from each other.

" *Storing.*—When the potatoes are quite dry and well sorted, proceed to store them thus: Mark out on the ground a space six feet wide, and as long as you please. Dig a shallow trench two feet wide all round, and throw the mould upon the space; then level it, and cover it with a floor of turf-sods set on their edges. On this sift or spread, very thinly, the dry mixtures, or any of the dry materials described below, and which you may call 'the packing-stuff.' Also, get some dry slacked lime, and dust all the potatoes with it as well as you can. Then put one row of turf sods, laid flat, on the top of the floor, all round the sides, so as to form a broad edge; and within this spread the dry potatoes, mixed well with the packing stuff, so as not to touch one another. When you have covered the floor in this manner up to the top of the sods, lay another row of sods all round the first, so that half of each sod may rest on the bed of potatoes, and the other half on the first layer of sods; this will make another edge one sod deep, which must be filled up with dry potatoes and dry packing-stuff as before. Then lay another edge of sods in the same way; fill it again, and so go on till the heap is made. When the building of this pit is finished, it may be covered with sods at the top, and will be ready for thatching. If rightly made, it will look like the roof of a cottage cut into steps.



" If you do not understand this, ask your landlord or your clergyman to explain its meaning, and we are sure that they will give you every assistance; also recollect that the recommendation applies only to sound potatoes, after being well dried.

" You will lose nothing by applying these materials in storing, for the turf can be burnt as you use up the potatoes, and the mixture of lime with dry sand, dry clay or ashes, which you are afterwards directed to employ, will form a good manure after having saved the potatoes. The only difference is, that you must get what you want now, instead of waiting till another time.

" After you have completed the heap, thatch it, so as to throw off the waters into the ditch and keep out the frost.

" In districts where there may not be spared turf sufficient to form the pits in the above way, make them as follows: Mark out the spot, and make the trench as before. Lay on the ground a floor of stones about as large as apples, and over them as much heath, brushwood, or twigs, as will just cover

the stones. On this floor form the heaps of potatoes, and packing stuff, just as described for the turf-pit. Cover the sides of the potatoes with more of the packing stuff, and thatch it in the usual way.

"We must again impress upon you that to put potatoes in your usual way is certain destruction to them.

"*Packing stuff.*—This, which is of the greatest consequence, may be prepared in either of the following ways—some of you may prefer the one, some the other:

"First way: mix a barrel of freshly burnt unslacked lime with two barrels of sand or earth, as dry as you can possibly get it. The lumps of lime should be broken into pieces as large as marbles, and the mixture should be left 24 hours; at the end of that time turn the heap well over, mixing together the lime and sand (or other dry materials) till no lumps of lime can be found.

"Second way: mix well equal quantities of earth and broken turf, or dry sawdust; put a few sods of lighted turf on the ground; place the mixture on them by degrees till a large heap is made; in a few hours the fire will have spread through the heap, which is then to be covered with earth so as to put out the fire. In fact, this is to be managed just as if you were burning land. This burnt mixture forms a very good kind of packing stuff; perhaps as good as the mixture of lime with dry materials.

"*What to do with bad potatoes.*—When potatoes are only slightly diseased, that is, when the disease shows itself only under the skin in small dark spots, or, at most, spreading into the substance of the potato for about a quarter of an inch deep, with a yellow, or light brown, or blackish color, without any smell, they may be eaten by the family without danger. They should be peeled, and the diseased parts pared off before they are boiled. The parts cut off should be kept for making starch. Potatoes thus treated are wholesome and palatable, but should be used for food as quickly as possible, as it is not quite certain that they will keep long without the greatest care.

"It is a pity to destroy potatoes for starch, if they will otherwise keep. Cut out the diseased parts, if it can easily be done, and dust over the cut parts with lime, and the potato also. Get them dry as soon as you possibly can; and if you have outhouses or sheds, you should keep the potatoes in them, also using the packing materials. In such cases you should allow the air to circulate freely in the sheds, and should frequently examine your potatoes, which should not be laid in layers above two or three feet in height. If you turn them frequently during the first two or three weeks, and keep them very dry, in this way they will probably keep. Although sheds or outhouses are to be preferred, if you have them not, and cannot construct them out of cheap materials, you should store the diseased potatoes by themselves, just as we have recommended you to store the sound ones.

"If, with all your care, the diseased potatoes still get worse, dry them thoroughly in kilns, or on hurdles placed over lime-kilns, or on screens or hurdles placed over low turf fires, after having cut the potatoes into two or three slices. It is only very bad potatoes that you should break up into starch.

"*How to save the value of very bad potatoes.*—Although nobody knows how to make bad potatoes into good ones, or to prevent many of them from becoming worse, yet it is possible to extract from bad potatoes, or from bad

parts of them, a great deal which is good. For this purpose proceed as follows. Provide yourselves with the following things: A rasp or grater, which may be made of a sheet of tin, or even of sheet iron bent round, and punched full of holes with a nail, a common coarse linen cloth, or hair sieve, hand sieve, or common cloth strainer, and a pail or tub, or two, to hold water.

"To make the bad potatoes useful wash them clean, and then rasp them into one of the tubs of water. The finer they are rasped, the more food will you procure from them. Having rasped a good many, take the cloth and place it on another tub; then put the pulp on the cloth, and pour water on it, allowing the water to run through. You have now two things to attend to —the pulp and the starch.

"First, attend to the pulp. Squeeze out as much water as you can from what remains on the cloth. You should wash it, however, till no smell remains. After you have squeezed it pretty dry, complete the drying on a griddle over a slack fire, and when it is dry put it aside for use.

"Next look to the milky water. It will then become clear, and the milkiness, which is starch, will have settled to the bottom. Pour off the water gently till the starch is tolerably well drained; then add more water, stir the whole well up, and let it settle again. As soon as it is again clear, pour off the water, and when you have got rid of as much as you can, put the wet lumps of starch on a shelf or other place to dry. In a few days it will be fit to pack up.

"Good wholesome bread may be made by mixing the starch with the dried pulp, peasmeal, beanmeal, oatmeal, or flour. You must bear in mind that starch is not food by itself.

"There will be of course a good deal of trouble in doing all that we have recommended, and perhaps you will not succeed very well at first; but we are confident that all true Irishmen will exert themselves; and never let it be said that in Ireland the inhabitants wanted courage to meet difficulties against which other nations are successfully struggling.

"ROBERT KANE,
"JOHN LINDLEY,
"LYON PLAYFAIR.

"Board room, Royal Dublin Society, *November* 3, 1845."

From the Gardeners' Chronicle and Agricultural Gazette, November 15, 1845.

FOURTH REPORT OF THE IRISH COMMISSIONERS.

Board-room, Royal Dublin Society,
November 7, 1845.

My Lord: Having laid before your excellency our views as to the best means of storing potatoes, and converting to useful purposes such as are too much diseased to offer a probability of being preserved, we now have the honor to bring under your consideration the question of seed for a future year. If in our former reports we have found it difficult to determine what course, under the peculiar circumstances of Ireland, it might be most advisable to pursue, we are still more embarrassed on the present occasion

in consequence of the conflicting testimony that has been presented to us, and the absence of all decisive evidence as to the cause of the potato disease.

The want of experience derived from previous visitations of the same nature, also renders it impossible to affirm in what manner the potato may be affected in the course of the next few months.

We have, however, endeavored to ascertain all that is positively known upon those subjects, by the examination of a great variety of published documents, both foreign and domestic, by personal observation, and by inquiries addressed to persons of practical experience or scientific reputation.

It is a very general opinion, and one entertained by men whose extensive knowledge entitles it to respect, that parasitical fungi, similar in their nature to those which produce mildew and dry rot, are the real cause of the malady.

It is stated that one of these plants, belonging to the genus "Botrytis," and similar to that which some years since produced great mischief among the silk-worms of France and Italy, has attacked the potato crop. It is described as entering the potato plant by the breathing pores of its leaves, and then passing down through the interior of the stem into the tubers, in which its mycelium or spawn fixes itself, traversing the cellular mass, separating the cells themselves, causing alteration in their chemical condition, and thus producing decay. In other cases, where the spawn is not apparently distinguishable in the diseased portions of potatoes, even by the most practised observers, it is suggested that the juices of the plant may be vitiated by the parasite which destroyed the leaves, and that particles of it, too obscure to be distinguished by the eye, may be circulating with the juices, and producing disease by irritation. The presence of the parasite is not to be detected by the naked eye, unless it makes its appearance on the outside of the potato in the form of mouldy tufts; but its spawn may be detected in the diseased portions by the microscope, whether any external indications of its presence can be perceived or not. Hence it is inferred that it is produced exclusively from within. It is, however, within our knowledge that, when apparently sound potatoes are pitted in places where the mouldiness of a diseased potato is able to appear, that mouldiness rapidly establishes itself on the sound potatoes at every point where their surface has been wounded or bruised, and that, under such circumstances, the disease is immediately extended through the entire mass.

That the spawn of fungi is present in large quantity in diseased potatoes is undoubted. The evidence of the best microscopal observers would be with us conclusive on that point, even if we had not verified the fact by personal examination. We also regard it as well ascertained that these parasites spread rapidly in warm and damp situations, producing infinite mischief under such circumstances, and that their advance is only to be successfully resisted by dryness. But it does not appear to us that their being the original cause of the disease has been well established. If it were so, it is difficult to conceive why fields of potatoes placed very near each other should be differently affected, or why certain varieties of this plant should be much more injured than others: the Irish apple potato, for example, which appears to have suffered more extensively than any other. We are also unable to reconcile with the theory of the potato disease being caused by parasitical fungi, the remarkable fact that, in its present form, it is certainly of modern origin. That it may have always existed is possible, though of this we have no proof; but at least there can be no doubt that it has only mani-

fested itself to any considerable degree within the last few years. We cannot suppose the Botrytis, which observers find to be the kind of fungus that attacks the potato, to be a recent creation. We must assume it to have been co-existent with the potato itself, and therefore we must conclude that some recent causes have come into operation favorable to its increase to the present alarming degree.

Without pretending to decide what that cause really was, we may state that it seems to be connected with the cold, cloudy, ungenial weather which has characterized the present year over the north of Europe; conditions highly unsuited to the constitution of a plant which, like the potato, is a native of a warm, dry, sunny country, and insufficient for the ripening of the tubers.

Without adverting to solitary cases, which require to be examined with more care than we have the means of giving to them, we may state, that amidst the mass of conflicting evidence which we have obtained, the following facts appear to be established:

1st. That potatoes planted early in the season are more healthy than those planted later.

2d. That the crop has suffered less in dry, elevated, sandy districts, where the influence of the season was mitigated by the slowness of the growth, or compensated for by the natural warmth of the soil.

3d. That the late varieties of potatoes are more diseased than early ones.

4th. That the present disease seems to be confined to the northern parts of Europe and North America, and to be unknown in the countries southward.

If we are right in the conclusion at which we have thus arrived, there will not be cause for serious alarm as to the crop of another year, unless an equally unfavorable season should be experienced, or the supply of healthy seed should be insufficient, or that the parasite should be found to have so entirely taken possession of this year's plants as to overcome the natural power of living bodies to repel the attacks of such enemies to healthy vegetation.

To Providence we must turn, in the hope that a second season like this may not be visited upon us. Should the Almighty, in his infinite mercy, avert such a misfortune, we entertain confident hopes that the two other sources of danger may be guarded against by human foresight and diligence.

In providing seed for a future year, we may look with confidence to such potatoes of home growth as shall have resisted all tendency to decay during winter; and we trust that a considerable quantity of them will be found remaining, where the precautions for storing, which we have recommended, shall have been observed. We do not anticipate any danger in the use of them, if they are planted early; especially if, before being planted, they are exposed to light till they become green. Another source of supply may, doubtless, be found in the southern parts of Europe, where, we have reason to believe, the disease has not shown itself; and we would strongly advise the public to lose no time in securing what may be procurable from that quarter.

It is stated by M. Seringe, secretary to the commission appointed in the department of the Rhone, in a report just published by him on the potato disease, that it is unknown to Genoa, and in the warmer countries. Our own advices describe the crops about Marseilles as being perfectly healthly;

and therefore we may conclude that mercantile enterprise will make up, by importations, a large part of the deficiency to be apprehended.

It has also been ascertained by actual experiment that potatoes, although diseased, will grow and produce apparently healthy plants.

The Rev. Mr. Berkley, a gentleman eminent above all other naturalists of the United Kingdom in his knowledge of the habits of fungi, and whom we have consulted on this occasion, states, that although there would certainly be some risk of raising a diseased progeny from a diseased stock, yet the growth of fungi so evidently depends on atmospheric conditions, that it does not follow that because germs are present they should be developed. We cannot, however, recommend the use of diseased tubers for seed, except by way of experiment, or in cases of absolute necessity; and it will always be prudent to dust them with powdered lime before they are used. It would indeed be proper to do so even when sets, however sound in appearance, are employed; for this process will destroy the minute seeds of parasitical fungi which may be sticking to the sets, and assist in repelling those which are lying in the ground; of course, those potatoes being selected which, on careful inspection, show no sign of disease, and hence afford the fairest prospect of a sound and healthy growth.

Where home-grown sets are to be employed for another crop, we would suggest with very great confidence the adoption of the system of autumn planting—a method of cultivation which has been proved advantageous in regard to the crop, which is attended with no unusual expense, and which seems particularly adapted to the circumstances of the present case. It has been shown by Mr. Grey, of Dilston, that in Northumberland his potato crop has been considerably increased in quantity by this practice, and that he has no disease in it this year. In 1844, his autumn-planted crop produced 100 and 111 loads, when the same quantity of spring-planted land yielded but 80 loads under the same circumstances.

And in the present season, this gentleman states that his autumn-planted is one-third better than his spring-planted crop. There can, therefore, be no doubt that the autumn-planting may be safely practised. On this occasion, it has these peculiar advantages—that it offers an additional chance of security against renewed attacks from parasitical fungi. On this point, the evidence of Mr. Berkley is positive.

"Autumn-planting," he says, "seems to me to offer the best chance of obtaining healthy sets. What are now planted will produce their tubers before the atmospheric conditions requisite for the growth of the parasite in the leaves can be realized; and without such growth, the particles, if present, will be too few to cause much evil. I think, under existing circumstances, the commissioners cannot do a greater service than by encouraging and enforcing as much as possible autumn-planting." Concurring, as we entirely do, in this recommendation, we trust that the planters of potatoes who have it their power to adopt it will do so at once.

All that we conceive it necessary to state, with reference to this practice, is, that it should be performed at any time before the end of January; that the sets should be thoroughly dried by exposure to light and air; that they should also be well dusted with lime; and that they should be planted in drills six inches deep, with farm-yard manure below the sets. We also recommend that where the potatoes are not large they should be planted whole, and even large potatoes should be cut into not more than two pieces.

We have ascertained that autumn-planting has already been practised

throughout Fingal, for the early supply of the Dublin market; and that although the practice has been nearly discontinued, that has not happened for any reason that affects the present question.

Neither can we learn that the early period at which the leaves appear above the ground in spring is attended with any greater risk than what attends precarious crops like the potato in any season. The effect to be anticipated from autumn-planting consists not merely in a probable increase of quantity in next year's supply, but in the saving of potatoes which may perish before spring, if the slow growth which goes on during winter is arrested, and in the early ripening of next year's crop, in the event of a second unfavorable season supervening. We may add, that experience has shown the small refuse potatoes of the year to be suited to autumn-planting, if sound, and prepared in the manner we have recommended.

It has been supposed by many persons that the potato has arrived at a state of general debility, and that the crop will continue liable to disease like the present, until new varieties shall have been raised from seed. We do not find any satisfactory evidence to support this opinion. It is doubtless true that great constitutional differences exist among the varieties of the potato, and that some are much more delicate than others; but we do not find that the oldest varieties are the most tender, or the newest the most hardy. On the contrary, it is within our knowledge that in the present season very healthy varieties, recently raised, have suffered much more than kinds that have been long in cultivation.

While, however, we withhold our assent to the proposition that newly raised varieties of the potato were exempt in any peculiar degree from the attacks of disease, we fully admit the fact that some varieties are much more subject to it than others; and we therefore recommend the cultivation of the tender kinds to be discontinued, and those alone be used for future cropping which the experience of the present year shows to be best suited to unfavorable seasons; and on this point we may further remark, that all concurrent testimony points out the Irish cup variety as that which has suffered least from the attacks of the disease.

We are also of opinion that it will be imprudent to plant potatoes for the next crop in land which has been just cleared of them. The latter is in all probability filled with the seeds of the fungi, countless myriads of which must have been scattered over the tainted fields; and although they probably have been borne by the winds to every portion of the country, yet it may be conceived that the soil will be more impregnated where diseased potatoes have just been growing, than in fields in which decaying matter was not absolutely present.

Under these circumstances, we are decidedly of opinion, that prior to putting any kind of crop, for the coming year, into land that has been this season under potatoes, it will be prudent, if not absolutely necessary, that the ground should be turned up and exposed to the action of the atmosphere with care, and that it should be thoroughly manured with lime. We have already recommended that the potatoes, whether whole or cuttings used for seed, should be dusted over with lime previous to planting; and we further urge that in the case of corn, or seed crops of every kind, the seeds should be steeped in lime water, or in the solution of bluestone and salt, well known to farmers. Evidence has already been laid before us of injurious effects where such precautions as we have described have been neglected.

We forbear from adverting to the possibility of replenishing the diminished supply of potatoes by sowing the seeds formed by the flower. This is an operation which can only be carried on successfully in a garden; is unsuited to the means of the small cultivator; cannot in any way affect the question of immediate supply, and may be safely left to the intelligence of the gardeners scattered throughout the country.

Hitherto we have laid before your excellency, for the purposes of publication, several reports in a merely popular form, suited to the present emergency. We are confident that the recommendations contained in them, if carried into effect, will tend to mitigate the evils arising from the attacks of the disease in the potato crop. We now propose to proceed forthwith to apply ourselves to the investigation of the important scientific questions involved in the subject, and to report in due time the results of our inquiries, in order that from past experience we may derive knowledge for future guidance. These investigations will occupy us for a considerable time, and while we do not contemplate the necessity of publishing furthur popular directions, we shall hold ourselves in readiness to give our immediate attention to any question which your excellency may submit for our consideration, or to report from time to time for your excellency's private information.

We have the honor to be, my lord, your faithful and obedient servants,

ROBERT KANE,
JOHN LINDLEY,
LYON PLAYFAIR.

FIFTH REPORT OF THE IRISH COMMISSIONERS.

ROYAL DUBLIN SOCIETY, *November* 8, 1845.

MY LORD: We take occasion to mention to your excellency some facts regarding the action of peat or turf upon diseased potatoes, which we are anxious to make known without delay; although at the present moment we do not wish to put forward a formal report, or official recommendation.

We had early fixed our attention on the preservative action of turf, and in our first report gave some directions for its use, since which time we have received accounts of its decisive utility in many cases. We had also obtained very distinct evidence that in wet, bog land the disease was in reality milder and less extensive than in drier and more fertile soils. Upon these grounds we proceeded to institute experiments on the action of bog water on diseased potatoes; and we find that certainly, when immersed therein, the disease appears to be arrested, and the substance of the potato does not appear in any way to suffer.

Our trials have been made in Dublin, and but on a small scale; and also the pressure of circumstances forcing us to make known every plan likely to prove useful without loss of time, we do not wish to have this notice considered as decisively stating that steeping in bog water will stop the progress of the disease; but we consider it highly important that the plan should be tried by persons residing in bog districts, where circumstances render a possible failure in a certain quantity an object of no importance.

We have accordingly applied to several gentlemen to institute trials on

a large scale, and shall, when we learn the results, at once proceed to lay them before your excellency.

We remain your excellency's obedient and faithful servants,

ROBERT KANE,
JOHN LINDLEY,
LYON PLAYFAIR.

On the first of these reports the public has still to pronounce judgment. It is at variance with opinions held in estimation by many careful inquirers, and it is probable that the correctness of the commissioners' views will be called in question.

The disputable matter may be divided into two parts. In the first place, the commissioners reject the theory of parasitical fungi being the cause of the evil, which they refer to atmospheric influences. As this is what has been always maintained by ourselves, it is needless to insist further upon that point until more proof shall have been brought forward in support of the fungal theory.

The other point is the wearing out of races. It has been repeatedly asserted that the reason why the potato is now suddenly attacked by a malaady which at one time threatened its destruction, is, that it has degenerated. This has more particularly been insisted on in a frothy pamphlet noticed in another column; and all on sides we hear of recommendations that new varieties of the potato should be immediately raised from the seed. In this, as in all other matters, it is easy to make assertions; but, before we give assent to them, we must ask for some proof of their truth.

Do the gentlemen who clamor for new varieties know which are the old varieties now cultivated, and which the new? Have they any proof that the old varieties have suffered in any peculiar degree, or that the new varieties have escaped? Can they point out any one instance among potatoes, in which facts support their views? We think not. At least they have not done so; and we therefore entirely agree with the commissioners in rejecting this hypothesis.

That the new varieties do not escape, we have the most positive proof. Doctor Maclean, a gentleman in all horticultural affairs, raised but the other day a seedling potato of great vigor and excellence. Its production is so recent that few persons yet possess it at all.

With this variety a portion of an old meadow, newly trenched over, near London, was planted in the autumn of 1844 and spring of 1845, no manure being used. The crop was so much attacked by the disease that not a single potato was found worth preserving; and the difference between autumn and spring planting, which Doctor Maclean's new potato was selected for the purpose of determining, could not be ascertained. In reality, there is no proof in any part of the vegetable kingdom that the races of plants wear out. Such an opinion was entertained, indeed, by the late Mr. Knight, and his views have been adopted by some physiologists. Yet there is not only no proof of their correctness, but the strongest presumption to the contrary. It is superfluous to say that the golden pippin apple is the instance on which this theory mainly turns. It is said that it has worn out, and can be no longer cultivated. But the golden pippin still appears abundantly in Covent Garden market: trees as healthy as ever are to be found in this country; we ourselves have seen it in Ireland, where there is no symptom of its decrepitude; and in Madeira it is in robust health.

The wearing out theory, therefore, falls to the ground. We observe the commissioners recommend all land which has borne diseased potatoes to be well limed before being recropped. They give no reason for the recommendation, but probably regard it as a prudent precaution against two possible dangers. It is improbable, but not impossible, that the myriads of seeds of fungi lurking in the soil may attack a new crop; that kind of danger will be arrested by the use of lime, which absolutely destroys such parasites. It is not improbable that decaying potatoes, left in the ground, may destroy such young roots as come in contact with them before the putrid matter has become decomposed; lime again hastens its decomposition, and therefore becomes a valuable agent in such a contingency. It may be that these fears are groundless, and that danger is not to be anticipated; but no prudent man, acquainted with the nature of plants, would venture to assert what will or will not follow in the train of such a pestilence as that which has attacked the potato. Professor Henslow, indeed, has furnished us with an instance of the deleterious effects of decaying vegetable matter upon young plants, which is particularly instructive at the present crisis.—*Ed. Gard. Chron.*

From the Edinburgh Witness.

INVESTIGATION OF THE POTATO DISEASE.

We are glad to learn that a special subscription is at present being raised among the agriculturists of Scotland, for the purpose of defraying the expenses of an investigation of the potato disease, or murrain, which is at present spreading so alarmingly throughout the three kingdoms. The proposed inquiry is to be chemical, botanical, entomological, and practical; the latter embracing inquiries as to the extent, appearance, and general characters of the disease in the different districts; the nature and condition of the soils in which it has appeared; the mode of treating and manuring the crops, &c. It is proposed to intrust this investigation to Sir William Jardine, Bart., of Applegarth, for the entomological branch; Dr. Greville, of Edinburgh, for the botanical; and to Professor Johnston and Mr. Fleming, of Barochan, for the chemical and practical part of the inquiry, with such other assistance as they may think proper to obtain. The sum required for this investigation is, we understand, five hundred pounds—a sum which, considering the vast importance of the subject, there will, we should hope, be little difficulty in collecting. The results will be published as they are obtained, and in a cheap form, so as to be accessible to all. The Highland Society has also offered a premium for analyses of diseased potatoes, the results to be sent in to them at the close of 1846.

POTATO ROT.

The Edinburgh Quarterly Journal publishes a letter from Professor Johnston, in which he remarks: "This disease in the potato has already called forth many hasty opinions, almost all *partially* true, because founded on one or two facts, but nearly all unsound as general expressions of the

truth, since they are contradicted by the experience of other practical men in other districts of the country. We are clearly unable as yet to assign either any general cause for the disease, or any universal remedy. Something may possibly be suggested by the analysis of sound and diseased potates, for which the Highland Society has offered a premium; though in the present state of our knowledge upon the subject, even this is doubtful."

From the Farmers' Library.

POTATO DISEASE.

Report on the cause of the potato disease, by C. Morren, Professor in the University of Liege; together with a preventive remedy.

It is known that a general malady has stricken the potatoes in Belgium, and it appears that the crop of this most necessary production is there much compromised. As it is said that this malady threatens also the potato crop in France, we believe it right to reproduce here the advice that Mr. Morren, Professor of Agriculture at the University of Liege, has addressed to the public in a letter that we find in "The Independence," of Brussels. Mr. Morren, after stating that this evil has for several years existed in Belgium, although in a less alarming degree, adds:

"The true cause of the evil is a mushroom, a mouldiness the learned will class in their genus 'botrytis,' but that the agriculturists hardly distinguish, which they call a burn, a fire, a stain, and which some attribute to humidity—others to dryness; some to a bad wind coming from France—others to insects, &c., &c. It is not, however, indifferent to us to know the true cause of the phenomenon, for this knowledge will put us in the way of diminishing the scourge, and possibly of destroying it.

"For some time I have followed every day, and step by step, the progress of the evil, in observing several fields of potatoes. The malady commences decidedly in the upper part of the leaves. I have even seen the flowers and fruits attacked in the first place. A part of the green tissue loses its tint and turns promptly yellow; the stain soon becomes more gray below, and it is always on the lower surface of the leaf, or on the fruit, where, a day or two after the appearance of the yellow stain, a whitish down shows itself. The microscope discovers then that this down proceeds from a mushroom which grows between the numerous hairs which garnish the bottom of the leaf of the potato. This mushroom is of an extreme tenacity; but it breeds and reproduces itself by thousands. Its stems are formed of little straight and partitioned threads, which have at their summit one or several branches, always divided in two; and at the end of these branches reproducing bodies develope themselves, which have the form of eggs, but which have not more than the hundredth part, or even less, of a millimeter in size. I may be told it is a very small body to commit ravages so great; but I answer, the itch is not the less to be feared because the animalcule which produces it is a microscope being.

"After the formation of the yellow spot, and the development of the 'botrytis' on the leaf of the potato, the stem receives the deleterious influences. Here and there its surface becomes brown, blackens, and when the phases of the evil are followed with the microscope, it is soon perceived that

the stem is attacked through the back. The morbid agent carries its action from the bark to the skin, and although this does not always offer mushrooms, it is not the less stricken with death ; for to any one that has some notions of vegetable physiology these effects easily explain themselves. The sap modified into living juice, into vegetable blood, forms itself in the leaf, and then descends into the stem and the root, by the bark. Here this sap is sick, modified—it carries the poison of the leaf into the stem, and this perishes. Indeed, so soon as the black spots declare themselves on the stems, the leaves become dry and die. Blackened and stricken with death by a venomous mushroom, they fall, unfortunately, to propagate the source of the scourge, or to deposite its germ in the earth. I will soon indicate the means which should be taken to prevent this fatal communication.

"The infection soon descends into the tubercle itself. If the evil follows its course, the tubercle immediately gangrenes. A potato is not a root, but a branch. It follows from that, that a tubercle possesses a marrow, which is the eatable part to be preferred, and a distinct bark. Between the marrow and the bark is found a zone of vessels which represents wood. One can easily understand this structure by cutting a thin slice of potato and placing it between the eye and the light. Now, the infection attacks the part which receives the descending sap—that part where the morbid agent has itself descended. Upon a potato being attacked, one perceives a series of livid spots, brown or yellow, sometimes gray or blackened—a series which extends itself throughout the woody zone. In following the process of the evil over a great number of spoiled tubercles, I could see how the disease, increasing by small degrees, finishes by reaching the heart itself of the potato, and corrupts it entirely. The skin of the sick potato easily detaches itself ; the flesh no longer cracks under the knife ; a discolored flaccidity, a fade, and later an animal smell, analogous to that of mushroom freshly cut, declares itself and carries off the heart. The animals even refuse to eat a food which may be regarded to be quite as injurious as deteriorated mushrooms themselves.

"So soon as the potato is gangrened within, that is, in its cortical part, but a few days, three at the most, are sufficient for the mushroom (the 'botrytis') to show itself without. This white efflorescence is seen to declare itself in the eyes of the tubercles, and then extend itself like light, white flakes, at first upon a rounded surface, but which finishes by invading the whole tubercle. The potato is then entirely lost.

"The source of the evil being known, all the attention of the cultivator should be directed toward the destruction of the mushroom ; for it is unfortunately too true that the blight, the rust, and all the race of parasites, once introduced into the country, they remain there and propagate themselves. This year the epidemic has been general—everywhere the germs of it exist ; millions of that which propagate it, if their number be not diminished, will attack plants the approaching year, and it will then be more difficult than ever to eradicate the plague, to do which it is essential to adopt the following means :

"1st. When the leaves are lost, they must be collected as quickly as possible, and burnt upon the spot, without being transported to a distance. The ashes may be spread upon the soil. In collecting them they must be shaken as little as possible. I have seen with regret the farmers collect the sick leaves, to preserve them in a pile in the field, or to cast them over the hedges. This is to preserve the plague for the next year.

"2d. When certain varieties of the potato, or certain localities, are free from the calamity at the time of the crop, it is always prudent to burn the leaves; for a field may appear clear of the 'botrytis' when it is not so. Several leaves are attacked; these leaves throw out the seeds of the disease upon the tubercles, which, preserved as seed, will preserve the disease the next year.

"3d. If the tubercles are themselves attacked, it is essential to take them out of the earth to make a prompt choice out of them, which is easy, for habit soon enables one to recognise the spoiled tubercles from those which are not so. The sound tubercles ought to be used as soon as possible, for they are not injurious up to the moment the bark becomes yellow. The smell alone is sufficient to detect the development of the malady. The sick tubercles should be burnt.

"4th. To obviate the sorrowful consequences of a crop which will be always reduced either a half, or a third, or even less than an ordinary crop, it would be important to follow, in our country, the method practised in Scotland in cultivating potatoes during winter.

"5th. Since it is very probable that the seed tubercles that may escape from the present crop will be infected with the germ of the mushroom, it would be well if, by the intervention of the government or commerce, the farmers had at their disposal pure seed tubercles, that were not infected; and for this purpose the potatoes of Pennsylvania or Ireland would suit us exceedingly well. The plague is not known in those two countries. We must distrust the potatoes of Germany, where the dry gangrene, the shrivelling, *(la crispure)* and the ulceration of the tubercle, are but too common; and we might take advantage of this importation to endow the country with those varieties of potatoes which are most congenial to our soil.

"6th. If the farmers are obstinate in employing, as seed, tubercles of this year's crop, it will be necessary to subject them to liming, as is done with wheat, rye, oats, and all plants which are subject to be invaded by parasites. The liming ought to be done by immersing the tubercles, because the study of the habits of the 'botrytis' shows it is the eye, the deepest point of the potato, which is attacked. The limed water should then bathe this leprous eye. Twenty-five kilog. of lime, one-quarter pound of the sulphate of copper, and three kilog. of marine salt, to 125 litres of water, constitute a liming of which the useful effects have been acknowledged by a great number of instructed cultivators.

"7th. In the plantings either of the winter of 1845 or the spring of 1846. it is essential to plant in potatoes parcels of ground as distant as possible from those infected this year, for it is easily understood that the chance of transmission, by the preservation, in the soil, of the seed of the mushroom, is much greater in plantings that approach each other than if they were made at a distance.

"8th. When the Counsellor de Martens visited Belgium, and inquired in our different provinces the state of our potatoes, he informed me, in one of his interesting conversations, that the farmers on the borders of the Rhine had remarked that the dry gangrene attacked oftener the potato plantings made in the afternoon, than those made in the morning; and he explained this phenomenon, which at first appeared singular, by a simple fact. When the sun has passed the meridian, the heat of the strata of air is at its maximum: this heat accelerates the vitality of plants; that which propagates them flies more rapidly in a dilated air; the insects,

in their flight, disperse with facility a mass of little bodies, of which the air is the vehicle; and the dissemination of their germs is then also at its maximum. The farmer is plunged in this atmosphere, and he causes to pass through it the potatoes which he plants; it attaches itself to the seed, and is sown with it; and that happens here which occurs to the grain not limed—the poison is sown and grows with the plant, to attack and kill it at a later period. From which arises the advice we give to the farmers, to plant their potatoes in the morning.

"9th. The employment of lime and marine salt, mixed with a small quantity of the sulphate of copper, is, as I have said, of a recognised efficacy in the destruction of the germs of parasite plants; consequently, to powder with these mixed substances the soil which has been planted with sick potatoes, is an operation calculated to destroy the germ of the scourge, and cannot be too strongly recommended everywhere.

"10th. The preservation of the potatoes that have escaped being attacked this year, in cellars, &c., will certainly deposite in these places the germ of the mushroom. To cleanse these cellars and whitewash them with lime, are excellent means of destroying the germs; and to spread lime and pounded coal on the places where the potatoes have been deposited, will finish the series of proceedings we consider the most rational, and the most certain to destroy, if it be possible, the evil at its root.

"CH. MORREN,

"*Member Royal Academy of Sciences, &c., University of Liege.*"

POTATO DISEASE.

To the Editor of the Durham Advertiser:

SIR: The investigation of the potato disease having been taken up on a large scale, I have been requested to undertake the chemical part of that investigation. I have in consequence drawn up the following queries for the purpose of obtaining information. They have already been widely diffused in the form of a circular. I hope you will have no objections to give them a still wider circulation through the columns of your journal, and you will oblige, sir, yours truly,

JAS. F. W. JOHNSTON.

DURHAM, *October* 27.

Queries in regard to the potato disease.

1. To what extent has the potato disease appeared in your district, or county, during the present year? Is the general crop large? and how much of it do you think is affected?
2. Is it more extensive during the present than during the past year?
3. How many years is it since it first began to be noticed among you?
4. At what time during the present season did it first appear in your neighborhood? Has its appearance been sudden and unexpected?

NOTE.—A letter from a Mr. Gilchrist, of St. John's, New Brunswick, dated 27th September last, contains the following passage: "I never was

more surprised at any thing than the change upon the appearance of the country from the time I had gone through it two months before. At that time every thing looked beautiful, and crops of every kind seemed abundant; but now a blight seems over every thing. From Halifax to St. John's I did not see a single field of potatoes but what was completely destroyed; and it is universal throughout the whole of North America. So bad are they upon St. John's river that the health officers have forbid them being brought to market; and from what the country people say, there will be scarcely enough left for seed. It is a strange sort of disease. It first attacks the shaw, and so rapid is it that in the course of two or three nights a whole field will be destroyed, and the stench that arises from them is almost unbearable."

5. What peculiar appearance has it presented? Does it differ in character from the disease of former years? Does it generally show itself in the leaf and stem before it appears in the bulb?

Note.—The rot in the tuber of the potato assumes two distinct characters, known by the names of the *dry* and the *wet* rot. The former, which has hitherto prevailed most in this country, has the appearance of brown or brownish-black streaks, spots, or layers in the potato, beginning at the outside and extending inwards, often to the very core. The affected potatoes often appear sound externally, though upon a closer inspection the seat of the disease may be traced by a slight wrinkling or discoloration of the skin. In many cases the disease appears first at the end of the potato most distant from the root. In others, it is the prominent eyes at the side of the potato which are first attacked, presenting a blue or livid appearance, and exhibiting, when cut, the brown fungus within. Potatoes with this form of the disease are often difficult to boil soft. When far gone, they have a disagreeable taste and smell after being boiled, and they not unfrequently decay after being pitted.

The *wet* rot forms an ulcer or distinctly decayed and rotten part in the potato. It sometimes appears as a rotten hole proceeding from the heel of the potato, where it is attached to the rootlet; sometimes it forms a soft mass over a large part of the surface, which can easily be pushed off by the thumb; and sometimes it appears sound externally, and yet may be crushed together in the hand.

The rotten portion has frequently the consistence of paste, "with tenacity sufficient to rope when held up, and the semi-fluid mass strings down like honey."

6. On what soils is it most prevalent; on light or heavy, on wet or dry, or on all soils equally?

7. Has it, to your knowledge, appeared on peaty or on newly broken-up grass lands?

8. In what varieties of potatoes? Have old or long cultivated varieties failed more than new or recently introduced varieties?

9. Are varieties raised from seed, to your knowledge, liable to failure?

10. Have potatoes planted whole shown any difference in the extent of failures?

11. Has the previous draining of the land any effect in preventing the disease?

12. Has the kind of manure applied any influence on the appearance or fatality of the disease?

13. Do you think the want of lime in the land is any cause of failure?

14. Does it, in your district, attack particularly fields or farms, and what are the peculiar conditions of these farms?

15. Does nearness to the sea or the use of sea-weed make any difference?

16. What is your opinion of the cause of the disease?

17. Do you think you have in any way contrived to prevent it during the present or past seasons; and how?

NOTE.—An American agriculturist says: "I have used slacked lime, which I sprinkle on the potatoes as soon as they are cut for seed, and shovel them over in it, and plant them immediately. Since I have adopted this plan I have not lost a potato, either in the ground or after they were put in the cellar; and such of my neighbors as follow my example are alike fortunate, and in no way troubled with the rot." This was written in 1844.

In Scotland, some practical men have supposed that, by the use of saline or chemical manures, they have been able to prevent it.

18. Has the peculiar wetness of the season, in your opinion, had any thing to do with its occurrence in your neighborhood?

NOTE.—The American Report for 1844 contains the following passage: "Notwithstanding the intensity of the drought, and its long continuance, the potatoes in this section of the country are rotting to such an extent as to destroy nearly the whole crop."

19. What are the first symptoms of decay after storing?

20. It is said that the rot spreads faster after the potatoes are put together in heaps or pits than when left in the soil, and late digging or leaving them all winter in the soil is therefore recommended. What practice would your experience lead you to adopt?

21. How would you recommend that the potatoes should be stored during the winter? Will a sprinkling of slacked lime, or of salt, or pounded charcoal, or charred peat, or wood ashes, be beneficial? Will washing the potatoes clean, and then picking and drying them before storing, help to preserve them?

22. What precautions would you adopt in preparing the seed in spring?

23. Have any cases occurred in your neighborhood in which the use of *diseased potatoes* has been injurious to animal life?

24. Are you able to forward to me any striking examples of *very healthy* or of very diseased potatoes from your neighborhood, or specimens of insects or of fungi you suppose to infest the potatoes, for the purpose of chemical, botanical, or entomological examination?

JAS. F. W. JOHNSTON.

From the London Mechanics' Magazine, &c.

ON THE POTATO DISEASE.

BY ANDREW URE, M. D., F. R. S.

The vague and contradictory statements concerning the nature of this calamitous visitation of Providence, as well as the directions for the treatment and preservation of the tubers, generally impracticable and preposterous, which have recently issued in vast variety from the press, do little honor to economic chemistry. It is needless to notice all the notions and schemes which have either officially or spontaneously been projected. On-

ly two of these deserve comment. The first as coming from a great master in science; the second as emanating from the Irish commissioners.

Professor Liebig imagines the essence of the disease to consist in the conversion of the albumen, a usual constituent of healthy potatoes, into casein, a principle which, by its great instability of composition, is supposed to cause the potato to putrefy rapidly.

I have subjected this opinion to the test of experiment. Perfectly sound potatoes, as also diseased ones, were sliced or grated and separately digested in a very dilute alkaline ley, at a blood-heat. The infusions, when cool, being filtered and faintly acidulated with dilute acetic acid, afforded respectively a like proportion of casein-looking flakes. It would thus appear, from this mode of testing, as prescribed by M. Dumas in the seventh volume of his "Tracté de Chimie," that *sound* potatoes contain as much as *unsound*.

Professor Liebig's plan of preserving diseased potatoes is founded on the above notion, and consists in cutting them into slices one quarter of an inch thick, and steeping them twenty-four or thirty-six hours in dilute sulphuric acid. On this proposal, I need make no comments, as it has no chance of being practised beyond the precincts of Giessen.

In the Pharmaceutical Journal for October last, I inserted a few observations on diseased potatoes, chiefly with the view of showing that till the putrefactive stage commences, the potato had the same acidulous reaction as in the sound state; but that *then* a portion of ammonia made its appearance, as was proved by its alkaline action on litmus paper, and by its covering over in distillation. That brief notice was written while I was at a distance from home on professional business, and where I had no means of prosecuting my experiments.

At my first period of leisure since, I resumed my inquiries, and have obtained certain results which may probably be found useful as well as interesting.

Before entering into a detail of them, I shall shortly describe the constituents of sound potatoes, according to the most authentic analyses.

Their average composition in 100 parts, according to Eenhof and Lampadius, is—Fibrous matter, 7; starch, 15; vegetable albumen, 1; gum, acids, and salts, 3.5; water, 75. Besides these principles, Vanquelin, by his older and more minute analysis, discovered the following in minute quantities: Crystalizable asparagin; an azotised substance resembling gum; a resinous matter, emitting an agreeable odor when heated; an extractive matter which blackens in the air; citric acid; citrates and phosphates of potash and lime. * * * * * * * * * * *

The nutritious quality of potatoes resides chiefly in the starch, fibrine, and albumen; the latter being essential to the formation of blood. * * *

In the diseased potatoes a portion of the starch is transformed into sugar, and of the albumen into an acrid offensive brown substance. If such tubers as are characterized by brown spots in the interior, and a thickened brown skin, both composed of fungus fibres, be grated or sliced and exposed to pressure, either alone or with a little tepid water, the juice obtained will be found to have a mawkish sweet taste, followed by a sense of pungency on the tip of the tongue.

If some of this juice be mixed with a little of Trommer's grape sugar test, (an alkalized solution of sulphate of copper.) this blue-colored mixture will change into a bright orange hue, slowly in the cold, but rapidly

on application of a gentle heat, with a deposite of protoxide of copper. By means of a modification of that test, described by me in the "*Pharmaceutical Journal*," for July, 1842, I have ascertained the existence of about five per cent. of saccharine matter in diseased potatoes; yet by the same re agent, which is sensible to $\frac{1}{100}$th of a grain of sugar, I could observe none of it in sound potatoes. After satisfying myself, in this way, as to the presence of sugar in diseased potatoes, I proceeded to verify the fact by placing their expressed juice, as also their infusion, in contact with a little yeast, at a fermenting heat of from 80° to 90° Fahrenheit, and watched the resulting phenomena.

A fermentative action soon began, and in an hour or two became so brisk as to throw up a thick creamy froth, like that occurring with small beerwort. At the end of thirty-six hours, the liquor having considerably diminished in specific gravity, was subjected to distillation, and yielded alchohol equivalent to about four per cent. of sugar in the potato. * * *

The vinous spirit produced is by no means disagreeble in taste or flavor, and may be easily rectified into excellent alcohol, fit for every purpose of arts, manufactures, and pharmacy.

Were it not for the oppressive laws of the excise, sufficient alchohol might thus be obtained this season for the uses of a temperate people, reserving an equivalent portion of grain from the whiskey manufacture for their sustenance.

The residual cake of the diseased potato is well adapted for feeding cattle, the morbid juices having been separated; and it may be so dried as to keep unchanged for a moderate length of time.

In all the diseased potatoes which I have examined with the microscope, the fibres of a fungus, called *botrytis*, from its grape-like form, or of one called *uredo tuberosum*, may be observed ramifying round the cells which enclose the starchy corpuscles. Now these plants, however minute, are not self-generated, but must be produced by some seminal impregnation, transported by the atmosphere, and peculiarly adapted to fructify, upon the *solanum tuberosum.* I would hence conclude that the potato disease is a peculiar vegeto-pestilence, diffused generally through the atmosphere, whose ravages have been favored by the sunless humidity of the last season, as the predisposing but not as the exciting cause. The proximate cause, again, in medical language, or the essence of the morbid state, is the fungus inmate of the tuber, from seminal impregnation of the stem, which so paralyzes the vitality of the plant that a portion of the starch and albumen becomes decomposed. This vegetable distemper, like that of the cholera, while general in its diffusion, is determined to particular localities and plants, by certain predisposing causes; yet it is independent of these, having occurred in many regions where such causes did not materially operate.

Whether it will recur, no human being can predict; meanwhile, it reads a great and solemn lesson to the rulers of states, never better expressed than in Virgil's well known verse:

"Discite justitiam moniti, et non temnere divos;"

which may be translated—"Beware of obstructing the free supply of food to your people."

Many preposterous prescriptions have been obtruded upon the public eye as to the best method of preserving the diseased potatoes from putrefaction. The above researches show the existence of a highly fermentable, saccha-

rine, and albuminous matter in them, which becomes rapidly operative by contact with air and moisture. Care should therefore be taken to keep their skins entire, so as to exclude the atmospheric oxygen and humidity. It is well known that the sugar in ripe grapes undergoes no change while the skin is entire; but the moment this is pricked, the grapes begin to ferment and speedily spoil. No plan is, therefore, more to be deprecated than that of slicing and mashing potatoes. They should be placed in an atmosphere kept by chemical means in a state of extreme dryness, which may be easily and cheaply effected by piling them upon a bed of brush-wood, dry turf, or straw, interspersing through the pile unslacked lime, coarsely bruised, and covering the pile thoroughly at the sides and on the top from the external elements. Since unslacked lime absorbs greedily one-third of its weight of moisture, it will bring the air in the spaces between the tubers into a perfectly arid state—a condition in which no decomposition of the substance can possibly take place. On the same principle, highly polished steel articles may be kept for any length of time without tarnishing in our humid climate, provided a basin with lumps of unslacked lime be enclosed in the case or chest containing them. Slacked lime, on the contrary, being saturated with water, has no power of dessication, but acts only, by its causticity, in favoring the destruction of all vegetable and animal matter.

Charlotte St., Bedford Square,
December 9, 1845.

PROFESSOR LIEBIG'S OPINION ON THE POTATO DISEASE.

The researches I have undertaken upon the sound and diseased potatoes of the present year have disclosed to me the remarkable fact that they contain in the sap a considerable quantity of vegetable casein, (cheese) precipitable by acids. This constituent I did not observe in my previous researches. It would thus appear that, from the influence of the weather, or, generally speaking, from atmospheric causes, a part of the vegetable albumen which prevails in the potato has become converted into vegetable casein. The great instability of this last substance is well known; hence the facility with which the potato containing it undergoes putrefaction. Any injury to health from the use of these potatoes is out of the question, and nowhere in Germany has such an effect been observed. In the diseased potato no *solanin* can be discovered. It may be of some use to call attention to the fact that diseased potatoes may easily, and at little expense, be preserved for a length of time, and afterwards employed in various ways, by cutting them into slices of about a quarter of an inch thick, and immersing them in water containing from two to three per cent. of sulphuric acid. After twenty-four or thirty-six hours, the acid liquor may be drawn off, and all remains of it washed away by steeping in successive portions of fresh water. Treated in this manner, the potatoes are easily dried. The pieces are white and of little weight, and can be ground to flour and baked into bread along with the flour of wheat. I think it probable that the diseased potatoes, after being sliced and kept for some time in contact with weak sulphuric acid, so as to be penetrated by the acid, may be preserved in that state in pits. But

further experiments are necessary to determine this. It is certain, however, that dilute sulphuric acid stops the progress of putrefaction.

GIESSEN, *November* 5.

From the Gardeners' Chronicle of November 15.

CAUSE OF POTATO FAILURE.

The cause of this disease appears to depend partly upon too great an amount of moisture, and partly on too copious a supply of manure to the soil: both induce too rapid a growth of the tubers, which renders the formation of a strong and durable cellular membrane impossible. Moreover, all the potatoes which have experienced the cell rot contain a much larger amount of aqueous constituents than the sound ones.

It may be expected that the disease of the tubers which are laid up for winter store will extend itself and finally destroy them, if care be not taken to preserve them in a dry place, whereby a portion of the excess of moisture may be removed. The author has found that the disease remains stationary when they are dried; at least, at the end of several weeks it had not attacked the neighboring parts.

PROFESSOR KUTZING.

From the Gardeners' Chronicle, November 29.

ROYAL AGRICULTURAL SOCIETY IN ENGLAND.

DECEMBER 9.—The first annual lecture was delivered this evening in the theatre of the Royal Institution, by Dr. Lyon Playfair. The subject was, the distemper in the potato. The lecturer commenced by making some general remarks on the history of the potato, and its cultivation in this and the other countries of Europe. He also exhibited diagrams of the structure of the potato, and tables of the chemical composition of the tuber in its healthy state. He then described the nature of the changes which took place in the potato under the influence of the disease. Much had been said and written with regard to the source of the disease; and since minute fungi were frequently found present in the decayed potato, the disease had been attributed to them as a cause. Some potatoes, apples, and other things had been inoculated with the sporules of the fungus, and these had become diseased. But if there were not some previous disease in the potato, how was it that some potatoes escaped whilst others were attacked? The disease he believed arose from physical or chemical causes. It was simply a decay of the tissue of the potato, arising from the union of the tissues of the potato with the oxygen of the atmosphere. When a decayed potato was examined, it was found that the diseased spots were always found in the region of the tissue called spiral vessels, whose function it was to carry air into the tissue of the potato. The reason why the cells entered into this decomposition so rapidly, arose from a constitutional weakness on the part of the cells of the tuber. This decay is rapidly spread from one cell to another, and the looser the tissue the more rapid the decay. By grating the tissue of some sound potatoes, and exposing it to the

atmosphere of the lecture room, it speedily assumed the color of the diseased potato. The cause of the constitutional weakness in the cells of the tuber was undoubtedly to be looked for in the weather.

A peculiar weather had been observed over the whole of the north of Europe, where the disease had been observed, as well as in America. The disease was no new thing, and appeared always when such weather occurred. At the time the plant commenced growing there was very warm and mild weather, and this was followed by cold and wet weather. The consequence was, the cellular tissue of the tuber contained more water than usual. In previous years, an analysis of the potato gave on an average 72 per cent. of water; by analyses which he had made this year of healthy potatoes, gave from 72 to 75 per cent. of water; whilst the analyses of diseased potatoes gave as much as 80 per cent. of water.

Other plants contained the same increase of water constituents, as turnips; and turnips were also affected with the same disease. Turnips were not so generally affected as potatoes, on account of their nitrogenous principles not being soluble, as those of the potato were. The disease, then, was a consumption of the potato, arising from the decay of its particles in combination with the oxygen of the atmosphere, produced by the state of the cellular tissue brought on by the weather. It arises from no degeneracy in the potato, and it need only to be feared from a repetition of the same circumstances. In the storing and preserving the potato, one great fact should be borne in mind; and that is, that the decaying particles were capable of communicating the decay to the sound tissue. Care, then, should be freely taken that they be freely ventilated, that they are kept dry and cool, and that there is absence of contact of the potatoes.

He defended the directions given by the Irish commissioners for the storing and preserving the potatoes as those best adapted for obtaining the object in view, in the community to which those directions were addressed. At the conclusion of the lecture, a vote of thanks to the lecturer was proposed by the Duke of Richmond, and seconded by P. Pusey, esq.

December 10.—Lord Portman in the chair. Dr. Playfair commenced by stating that the object of the lecture this evening would be to point out the mode of treating the potato for the future; and first, with regard to planting. He recommended that the potato should be planted *immediately*, for several reasons. First, because there might be little left for seed in the spring. Second, because potatoes planted now might be ready for use at the latter end of May, or the beginning of June. Where economy of seed was not necessary, he thought it would be better to plant the whole tuber of the potato, than to cut it. Where economy of seed was necessary, single buds or "eyes" of the potato might be removed and planted, the rest of the tuber being used for food. With regard to diseased potatoes, he recommended that they should not be used for seed where sound ones could be obtained; but where these could not be got, then he advised the planting of diseased potatoes rather than none at all. There was no prospect of obtaining sound potatoes from abroad for seed, and he had the permission of the late government authorities for stating that this was the result of their consular returns. If he were right in his views with regard to the nature of the potato disease, then no evil can arise from planting potatoes in the same soil in which they had become diseased. The fungus theorists objected to planting potatoes in the same soil; but he had shown their theory to have no foundation in facts. He would now consider how

the bad potatoes might be used, and quoted Bonjean's experiments to show that no injurious effect was produced on the system by eating them cooked; they might, when boiled, be safely given to animals, which would thrive on them. He described the various processes of procuring the starch which had been brought before the public, and pointed out the fact, that in procuring the starch only one of the alimentary secretions of the potato was obtained—that which assisted in keeping up the animal heat. The nitrogenous portion is thus lost. The plan he recommended, by which these last might be saved to a great extent, was to grate the potato, and pour water upon it till no more soluble matter was taken up: the remaining in soluble substance should then be dried, when it would be found an excellent meal with which to make soups, puddings, bread, and other articles of food. He did not apprehend a scarcity of food, but he wished to point out the fact that potatoes contained a very small portion of nutritious or nitrogenized matter; and, as this was the most important constituent of a working man's diet, he had drawn up a table of the comparative expense at which various articles of food might be obtained, which contained one pound of this nitrogenous matter:

25	pounds of	milk	contain one pound of	protein;	price 3*s*. 6*d*.
100	do	turnips	do	do	2*s*. 9*d*.
50	do	potatoes	do	do	2*s*. 1*d*.
50	do	carrots	do	do	2*s*. 1*d*.
4	do	flesh	do	do	2*s*. 2*d*.
9	do	oatmeal	do	do	1*s*. 1*d*.
7½	do	barleymeal	do	do	1*s*. 2*d*.
7½	do	bread	do	do	1*s*. 2*d*.
7½	do	flour	do	do	1*s*. 2*d*.
3½	do	peas	do	do	7*d*.
3½	do	beans	do	do	6½*d*.

He drew attention to the importance of cultivating the leguminosæ with such plants as the potato, on account of the large quantity of nitrogen they contain. In conclusion, he hoped the present blight would direct attention to the potatoes as an article of diet, and lead to a much less extensive dependence on them as food—a dependence of which they were unworthy; and, in the end, this dreaded visitation might prove a national blessing.

THE POTATO DISEASE IN FRANCE.

The extraordinary disease which has destroyed the potatoes in England has extended its ravages over Belgium and the north of France. In the latter there has been a complete panic on the subject, and, according to a statement in one of the Rouen journals, the mayor of one commune ordered that no travellers were to be supplied with potatoes. The Central Society of Horticulture for the department of the Seine Inferieure deputed a commission to visit the spots around Rouen where the potato is cultivated. Immense fields were found entirely destroyed. In all the neighboring districts the disease was found to be prevalent. In fields with a north or south aspect, having a good or bad situation, in all sorts of soils—stiff clayey, light sandy, deep, and shallow—the disease is the same. The only differ-

ence is, that the red potatoes are less affected by it than the others. The disease begins at the stalk : small black spots make their appearance ; they increase, and spread, and multiply, till in the end they cover the whole stalk. It begins on the surface, and soon sinks beneath it ; the vessels of the plant then take up the virus—it descends with the juices, and destroys the texture of the plant. The stalks dry and wither. The leaves die the last. The virus being carried to the tubers of the descending sap, small black spots appear in the middle of the potato ; they enlarge and spread. When the disease reaches the skin, the starch or pulp decomposes and becomes dry, hard, and black. The skin breaks ; decomposition is then complete, and the potato is rotten. It is supposed that the cold nights and the rain have caused this disease. The stalks look as if they had been frozen. The commission learnt that the peasants have given these diseased potatoes to their cattle without causing them any injury. The commissioners, therefore, had some of those which were just spotted boiled for themselves, and partook of them without inconvenience. The amount of the crop destroyed in the north of France is estimated at one-fifth of the whole.—*Rouen paper.*

The potato crops have failed in considerable portions of the provinces of Antwerp and Brabant. In Limburg and Luxemburg not a single locality has escaped the infection, but the light soils have less suffered. In western Flanders the greater portion of the crop is lost, and in eastern Flanders only one-fourth of the spring potatoes and nine-tenths of the less forward kind can be used. In Hainault the devastation has been very extensive ; and in all parts of the provinces of Liege and Namur the disease has raged more or less. In fact, it may be broadly asserted that the potato crops have all but universally failed here.—*Mark Lane Express.*

THE POTATO CROP ON THE CONTINENT.

Accounts from Stenay, on the Meuse, state that the disease with which the potato crops have been attacked in French Flanders and Belgium has extended to that country. The tubercles, the stalks of which are speckled, proved to be completely soft and full of water, and are unfit for food. The *Gazette*, of Metz, also announces that the contagion has affected several communes round Sarreguemines, in which the damage is greatest in the strong wet lands. Here the potatoes are so deleterious that they cannot be given with safety even to cattle. This scourge has fallen upon the districts of Sarrelouis and Leybach insomuch that petitions have been presented to the Prussian government for a suspension of all distillation from potatoes.—*Mark Lane Express.*

THE POTATO CROP IN DENMARK.

We have accounts from Copenhagen, which state that the disease in the potatoes is spreading more and more in Denmark, as in Funen, Lolland,

Falster, and likewise Sealand; especially in Amak, near Copenhagen. It has likewise appeared in the Duchy. It is stated that the disease is beginning to show itself in Sweden; and as the crops, particularly of the latter kinds, are more backward than in the Netherlands, it is feared that the disease may spread wider. It will, therefore, be advisable to take measures, in the discharging of cargoes from that country, to ascertain the quality of the potatoes.—*Dutch paper.*

THE POTATO DISEASE.

Paris Academy of Sciences: sitting of September 15.—Several communications were received relative to the disease which has this year manifested itself in the potato. The writers who treat on this subject, scientifically, are divided in opinion as to whether the disease is the result of the invasion of a parasitical mushroom, or solely attributable to the unfavorable nature of the season. One writer thinks that the parasitical invasion alluded to is common to the potato, and that it has been developed more extensively by the coldness and dampness of the summer. With due deference to the scientific gentlemen who have turned their attention to the visitation, we beg to observe that it is comparatively of little importance whether the disease have one origin or the other. The great questions to be considered, are, first, whether the diseased potato is, as people suppose, generally poisonous, or in any way injurious to health; secondly, whether, supposing this not to be the case, the disease has deprived the tubercle or its nutritive properties; and, thirdly, whether these diseased potatoes can be used as seed for the next year's crop. M. Philippon and M. Pouchet say that they have eaten potatoes in their diseased state, without suffering from them in any way. This is tranquillizing news; but these gentlemen do not tell us to what extent the potatoes which they ate were diseased, or whether, supposing that the diseased potato is not poisonous, it has not in its affected parts lost all its farinaceous character. We have examined diseased potatoes of the present year in all the stages of the disease, and have eaten some of those which were least infected—first, however, removing all the unsound parts with a knife—and certainly we did not experience any ill effects. This shows that the malady has only invaded such parts of the tubercle as give evidence of its existence; and there cannot be the least doubt that such parts as remain sound are fit foor food, whether for man or beast. As to the diseased parts, we have no hesitation in saying that they are wholly unfit for food, whether they be poisonous or not, for they can have no nutrition whatever. As to whether the diseased potatoes may be safely used as seed for the next crops, we do not think it requires much science to give an answer. If any part of the potato remain unsound it may germinate, and produce as good stock as that from a potato that is not diseased; and it is very improbable that the diseased portion should have the power of propagation, for it is a mass of putrid matter; but it remains to be seen whether the malady will not continue its ravages between this time and the period for planting, and so deprive the tubercle of all power of propagation.

REPORT OF THE COMMISSION OF AGRICULTURE OF THE PROVINCE OF GRONINGEN, ON THE DISEASE AFFECTING THE POTATO IN THE NETHERLANDS.

1. *Causes and nature of the disease.*

The agricultural commission is of opinion that the disease is not occasioned by any direct cause, but rather that various circumstances have combined to give the disease this year an extraordinary impulse, it being, in the opinion of many scientific persons, not a new scourge.

The primary cause may be attributed to the extremely wet summer of 1845, and to the heavy rains which fell at the moment of the formation of the tubers. It is probably owing to this circumstance that many plants did not germinate. In the second place, the commission is of opinion that the growers do not sufficiently attend to the preservation of the potatoes used as plants, so as to keep them from all damp. It is also very probable that the intense cold in the month of March much injured the tubers.

The more direct causes are probably as follows:

1. The too rapid development of the plants this year. It is well known that those plants which spring up too quickly, and the grain sown on an over-manured soil, are subject to such diseases as ergot for rye and other cereal grains, and rust for wheat, and the presence of cryptogamous plants.

2. The intense heat in the early part of the summer of 1845, and which amounted on the 13th June to 87° Fahrenheit, on the 3d July to 87½°, and on the 7th of July to 91½°, necessarily had the effect of drying up the ground excessively; and the rain which fell at intervals during the continuance of the hot weather, and was soaked in, had the effect of scorching, as it were, those plants and potatoes which, not being very deeply planted, were exposed to the action of the heated water.

3. This intense heat was succeeded by cold and rainy weather, which lasted from the 15th of July to the end of the month of August. This damp weather, and the total absence of the vivifying rays of the sun, caused a kind of rottenness among the pithy plants, and especially developed the cryptogamous plants.

4. On the 21st and 22d of July, an extraordinary fog was perceived in many places, which spread a disgusting smell. Soon afterwards, on the 28th of July, the first symptoms of the disease were discovered in the provinces of Groningen and North Brabant; and it is more than probable that this fog, which was epidemical, was intimately connected with the disease.

According to all the experiments and descriptions made of the disease, it appears that it commences on the upper part, and then attacks successively the leaf, the stalk, and the tuber. This is fully confirmed by an experiment made at Groningen. As it is the upper part of the stalk which is generally first attacked, it is probable that the disease originates in the leaves, descends the stalk by means of the peel, and then communicates with the part below the ground.

5. On the leaves spots have been perceived, and also a kind of fungus described in the work of MM. Maleschott and Baumhauer, and classed by M. de Martius among the *Fusisporium Solani*. These fungi are similar in every respect to those drawn by the above gentlemen.

It is very probable, then, that the above enumerated circumstances have been the simultaneous causes of the plant rotting, and of the fungi which

are observed thereon. It unfortunately happens that these fungi, which are extremely minute, are quickly propagated to an inconceivable extent, favored by the dampness of the atmosphere.

But the principal cause, or rather the character of the disease, is a kind of gangrene or mouldiness in the leaf, which occasions a very hurtful and even mortal decay to the plant. The dangerous influence of the cryptogamous plants has long since been shown by the example of the rust *(uredo rubigo)* in corn.

As soon as the rust spot developes itself on the leaf of the wheat or oak plant, it is observed that the leaf turns yellow, and withers at the spot where the rust shows itself.

No traces of the fungi have been found in the interior of the stalk or in the tuber. The commission, therefore, considers that the disease of these parts results from that of the leaf.

It is very probable that the disease has long existed in this country, but it has never hitherto sufficiently developed itself to attract serious attention. Having been fed for two years by a moist temperature, it has increased this year to a frightful extent, and become a real calamity. The commission is, however, of opinion that the disease, as now known to us, has never been treated of by naturalists. At any rate, it is far from resembling the cancer described by De Martius, or the scurf of potatoes, as these two diseases arise in the tuber, and not in the leaves.

2. *Remedies for the disease.*

The disease itself, its character, and causes, having now been sufficiently considered, it is necessary to consider the remedies for the disease, of which the commission points out three different kinds:

I. A means which, unfortunately, it is not in our power to adopt at pleasure—that is, a drier atmosphere; for if it be damp that has caused the mouldiness of the leaves, and has propagated it among the plants, it follows that dry weather would put a stop to the ravages of the disease, and even result in entirely destroying it.

This observation applies to the measures which science may propose, now that the disease has probably reached its period.

II. To prevent the return of the disease, it is necessary to take the following precautions:

1. To leave the potatoes in the ground until very dry weather occurs. Experiments having shown that their decay is accelerated by being taken up, it is advisable to leave them in the ground at first, in order to get dried, and afterwards to lay them out over the field. This would have the double advantage of rendering the vegetable more whole some, and of preserving it.

2. The following applies especially to those potatoes to be used as seed for next year. It is necessary to beware of planting those plants which have been attacked by the disease. They must be carefully chosen from those whose stalks have not been attacked, and placed in a situation free from the slightest damp. As the disease has been less severe in gravelly than in clayey soils, the tubers should be chosen from those gravelly soils where the disease has not penetrated.

3. The withered leaves of diseased potatoes, which are of no value,

should be immediately burnt; the same should be done with the rotten potatoes, which cannot be of any use. Nothing should remain of them.

4. It is necessary to avoid as much as possible planting potatoes in the same spots where they have been planted this year, for it is most probable that seeds of the fungi have remained in these places, and there would be great risk of the ensuing crop being similarly attacked. It is also necessary to manure the land with lime after the potatoes have been taken up, and then to clear it; and if the land be employed for produce which need not be planted before winter, it is better not to harrow it, and so allow the air and cold to penetrate it. In the spring the lime manure should be renewed as much as possible, and the land may be watered with diluted sulphuric acid, one part of sulphur to 100 of water.

5. Next year the potatoes should be planted in dry land; all damp places should be avoided, even places shaded by houses or trees. It is once more repeated that great care should be used in selecting the tubers, and they should be planted at a little distance from each other, so that the earth round each plant may be raised, that the air may penetrate everywhere.

6. The commission does not agree with those naturalists who think that the origin of the disease may be attributed to the race of potatoes having gradually deteriorated, owing to their being seldom reproduced in fresh soil. The report mentions that in the commune of the Marum, (province of Groningen,) among other instances is to be seen a field of potatoes, the produce of only three years' culture, equally attacked by the disease; and an infinite number of similar cases prove incontestably that the potato has not degenerated. However, the commission recommends that fresh seed should be employed this year; for it will then, at any rate, be certain that it has not been attacked by this scourge.

III. If, notwithstanding every effort, the disease should again break out next year, the moment the first symptoms of it are perceived, the first leaves that turn yellow should be taken off and burnt, or the entire field should be watered towards evening with lime water, or, still better, with diluted sulphuric acid, so as to destroy the seeds of the cryptogamous fungi: sulphuric acid, moreover, prevents rotting, and, when prepared as above directed, can do no injury to the plants themselves.

3. *Use to be made of the diseased potatoes.*

Those potatoes which have been attacked by the disease appear not to be prejudicial to health, when taken in moderate quantities. The commission has consulted veterinary surgeons as to whether the potatoes can be employed, without danger, to feed cattle. Their reply was in the affirmative. It has been proved, moreover, that pigs have eaten the diseased potatoes without death ensuing. The commission is, however, of opinion that they should be cooked beforehand.

Man may likewise make use of the diseased potatoes, but must carefully remove the brown spots which caused the disease. It has also been shown, by experiments, that potatoes which have remained untainted on the same plant where there are spoiled tubers may be eaten without hesitation. It is almost useless to remark that potatoes which are completely rotten are hurtful not only to man but to cattle, and too frequent use of spoiled potatoes is equally dangerous to those who make their sole food of them. Dr. Westerhoff remarked, that in the commune of Warffum (province of Gronin-

gen) those persons who made use of spoiled potatoes experienced pains in the stomach, and nausea, followed by vomiting, after eating them.

It has also been perceived that sheep have been made severely ill by eating attacked potatoes, though they were soon cured by a change of food.

As to the means to be employed to prevent the baneful influence that my be exerted on the health of man by eating the diseased potatoes, the commission proposes to make this the subject of another inquiry. In the mean time, it advises that as much use as possible should be made of the fecula of potatoes.

From the London Gardeners' Chronicle, Nov. 29.

POTATO DISEASE IN BAVARIA.

This is fortunately not very common in our part of the continent. I do not think we have yet lost more than the tenth or twelfth of the crop. It is everywhere more observed in wet, heavy land, than in such as is dry and sandy, or chalky.

It is distinguished from the disease that attacked us in 1842, by the rapidity with which the infected potatoes run into a state of putrefaction, by the absence of any evident fungus spawn or mycelium, and by the obliteration of the membrane of the cells before any diseased action is visible in the starch grains. I am perfectly satisfied that it is the extraordinary season, combined with the negligence of our cultivators, and their bad treatment of the plant, that have caused us to be visited with this calamity. I cannot believe that any parasitical fungus has produced any such mischief. This year the parasite *aecidium columnare* has done great mischief to the spruce fir trees on our Alps. The trees have been much weakened by the loss of the leaves of 1844 and 1845, which were loaded with the parasite; but leaves of a greater age have not been touched. The young leaves had assumed a dull yellow color before they were attacked, and this disease, which was the precursor of the fungus, was no doubt caused by the long duration of an extraordinary lodgement of snow during the past winter, and by sudden changes of temperature (as much as from 30° to 5° R. in three days) during the summer. "*Je n'aime pas à vou des revenants dans la nature.*"

ZUCCARINI.

MUNICH.

POTATOES FROM SEED.

[Made public by order of the Minister of the Interior.]

The disease in potatoes, which has this year appeared in many parts, has rendered it necessary to raise them from seed; but as the old method required several years to produce tubers of a sufficient size, it is little practised.

Zauder, Count Arnim's gardener, at Boitzenburg, (in Mecklenburg,) has succeeded in producing a good crop of potatoes from seed the same year it

was sown, and as large as those from sets, and those seedling potatoes are entirely free from disease. His plan is as follows: He gathers the apples before the frost sets in, (according to others, a slight frost does not injure them,) and keeps them in a dry place till the end of January. The apples are then crushed with the hand into a vessel, where they lie from six to eight days to rot, that the seeds may be easily separated from the pulp. Water is then poured on, and the seed is washed and dried like cucumber seed, and put away in a dry place. At the end of March, or beginning of April, the seed is sown in a hot-bed, and treated much the same as other culinary plants. If there is a convenient place for a hot-bed near a wall or house, exposed to the sun, glass is not necessary. The plants may be treated like tuberous plants; but as they are very susceptible of frost at night, they should be covered with straw or boards, which can easily be done, as the bed is surrounded with boards set in the ground, upon which the covering can be laid without injuring the plants. In May, if the plants are well grown, they can be planted out in a light soil about the usual distance that sets are planted. Zauder this year sowed early potato seed on the 11th April, and planted them out on the 26th May; and here we may remark that vegetation is 14 days later in Boitzenburg than in Berlin.

The plants produced from 1 to 1½ gallon (metzen) of tubers. One plant even produced 280 tubers. There were of course a great many small tubers among them, yet the produce of large ones was, on the whole, equal to the produce from sets. As Zauder has followed this plan for five years, he was able this year to give seed to several gentlemens' gardeners and laborers. The potatoes raised by them have all been healthy, while the disease was everywhere, and even in the neighborhood. The result of this experiment deserves to be widely spread, that the people may still preserve the apples for next year. The space of half a square rood of land (7 feet) is sufficient to raise enough to plant one acre, so that it will be useful for small farmers who plant just enough for themselves.—*Preussische Zeitung.*

From the New York Farmer and Mechanic.

The following communication was read before the last meeting of the Farmers' Club, and communicated to the Farmer and Mechanic:

AN ESSAY ON THE WET AND DRY ROT IN POTATOES.

BY FRANCIS AUGUSTUS PINCKERT WEIMER.

The crops of potatoes in mountainous districts are found to be invariably of better quality, and larger in quantity, than those raised elsewhere.

In former years only single potatoes have rotted here and there; still it is only within the last few years that the malignant and destructive potato rot has commenced.

Extent of this disease.—In Bohemia, believed to proceed from insects; in Saxony, in Russia, especially in Pomerania, Silesia, Westphalia, and Rhenish Prussia, in the mountainous country of the Lower Rhine, loss of half the crops.

In Arnsburg, in 1840, potatoes cut and planted rotted in the ground. In 1839, *whole* ones did not germinate. The rot not owing to dry weather.

In Bavaria potatoes rot sooner than they did six years ago. Those from the other side of the Rhine being planted, they were no better. In Austria and Prussia, particularly in Gera, this disease exists. In some fields not half of those planted germinated. In the midst of all these, we were delighted to see the fields of *Von Meutzch*, with fine luxuriant crops of potoes, owing to the rational mode of cultivation.

Many tenants who had raised several hundred pecks of potatoes now had but twenty or thirty pecks.

In Hesse and Nassau, Mechlenburg and Anhalt, the crops of 1842 were very diseased.

In 1780 and 1782 there was a potato disease, but only of the stems and leaves.

In England and France the disease is complained of greatly.

In Denmark, in Sweden, and in Norway, it is found.

In the Russian provinces on the Baltic it appeared in 1843, and the seed potatoes procured from a distance suffered as well as the native seed.

This disease shows itself by perfectly obliterating the whole internal organic structure of the potato plant. It is of two kinds—the *wet* and the *dry* rot.

Professor Kohlert, of Prague, terms the dry rot a *cold combustion*. They have white spots on them called combustion spots.

In Nassau, the potatoes, after digging, show on their outsides brownish red spots. After being in the cellar some time, they become spongy, cavities commence in them, and a very bad smell.

In Saxony, they say the spots were black, and they term them corruption spots.

Kleeman says the dry rot does not always affect all the potatoes in the same field at the same time, or same extent; that the eyes are first affected. In 1841 he first observed numerous brown or black spots on them, called *stagnation* spots.

Kohlert says the wet rot causes the potato to become spongy, moist; and, being compressed, resemble rotten cheese, and also have a putrefying smell; and such ones infect sound potatoes in contact with them.

In Thuringia, potatoes had the wet rot. Formerly they had been injured much by worms. A field which had never before been planted with potatoes showed the same disease.

DISEASE OF THE POTATO.

[Translated by H. Meigs, esq., Secretary of the New York Farmers' Club, from the Annales de la Societé Royale d'Horticulture de Paris, November, 1845.]

Note by M. Payen on the special affection of potatoes in 1845:

Progress of the disease.—This special affection of the potatoes has extended from Germany to Belgium and to Great Britain, and afterwards to France, where it has spread by degrees in the departments of the north, northwest, centre, south and east, moving step by step, attacking all varieties of soil, situation, exposure—sparing here and there spaces of more or less extent, or circumscribed in the midst of diseased fields.

In the midst of this confusion, we have generally remarked varieties of

potatoes ripening very rapidly, some later escaping the evil. Dry, sandy, sloping soils, open to the south, may be little or not at all diseased.

Causes.—All observers agree in acknowledging the influence of extraordinary weather: cold in a very wet summer—intervals of great heat and storm.

The luxuriant growth of the potato stalks promised a great crop; but the tissues having pores thus widely opened, distended with the wet which the plant could not exhale, were easily dislocated by sudden cold, and more generally in this condition they received the germs of the cryptogamid, whose sporules penetrated through the conduits of the stalks, so full of liquid, to the tubers. We conclude that the disease consists in the development of cryptogamous vegetation from sporules, introduced into the potato through the stalks. This parasite vegetation often attacks only those potatoes nearest to the bottom of the stalk, sparing almost always those potatoes which are second or third in growth on the roots of the plant.

This cryptogamous vegetation and the diseased potatoes are then attacked by various insects, which have been carefully observed and described by Messrs. Rayer and Guerin Meneville. Putrefaction then fills the tissues with fungus, and, besides, they are attacked by myriads of microscopic animalculæ, which, in their turn, decay and add their ruins to the putrefaction.

One rational mode of preventing this disease would be to burn the potato stalks, so that we may destroy as many of the sporules as possible. But many would still escape. Better seasons than our last may doubtless suspend or diminish this evil. We ought to plant our crops of potatoes as far as possible from the fields where they were diseased.

We ought to plant them on dry, sloping lands, rather than wet and low grounds. We ought to plant such potatoes as ripen early. We ought to plant all the varieties of potatoes from fields not yet diseased. Lime the potatoes for planting, and give the soil some lime. Watch the growth of the potato stalks, and as soon as they show signs of disease cut off the stalks, take them away, and burn them. When the potatoes are approaching maturity, watch the leaves, and take off such as show disease. Whitewash with quick-lime (one part lime to twenty parts boiling water) the walls of the cellar where you store the potatoes.

Lastly, to renew from the seed the variety of potatoes offers the best chance for the amelioration of our potatoes.

Note by M. Mounier, of Bourg.—In the department of Ain, potatoes were not diseased, but they showed a precocious and unusual maturity—some three weeks earlier than common. We hoped a great crop (about the last of July;) but all this anticipated maturity paralyzed the growth of the potatoes, so that, although one crop was good as to the quality, yet the potatoes were small and few in number.

From the Farmers' Cabinet, February, 1845.

DISEASE IN THE POTATO.

A committee was ordered, by the Philadelphia Agricultural Society, some time since, to collect facts and materials for a report on the disease of the potato now prevailing. As a part of their action, the following translation was made, at their desire, of a paper on the subject, by Professor Von Mar-

tius, one of the most celebrated scientific men of Europe; and they now publish it as a part of the report that they intend making at some future time.

The potato epidemic of last year, or the rot and scab of the potato, described by Dr. C. F. Ph. Von Martius: Munich, 1842.

Certain diseases of the potato plant have been observed for more than eighty years.

Curl.—The *curl* has been observed in 1776–'79, in the principality of Goettingen, and was described first in 1779. The so called white table potato was almost the only sort attacked at first. In 1780–'90, the disease appeared frequently on the British Isles, where it is said to have been first observed in Ireland, whence it spread over England and Scotland. John Holt mentions two other diseases, as having appeared contemporaneously with the curl, viz: the cancer, which appeared, according to him, chiefly in wet seasons; and the scab, which appeared to be produced by dry seasons.

In Hanover, the curl was first observed by Thaer, in 1790, and in the beginning of this century it showed itself most destructively in Southern Prussia, since which time it has shown itself at different places in Germany; nowhere, however, to any great extent. Putsche, a monographer of the potato, gives the following description of the curl: The plants attacked by it look very poor; stem of a brownish green, or of a variegated color, with rubiginous spots, penetrating into its pith; leaves rough, wrinkled, curled, shrunk, with short petioles, covered with spots—some of a light green, others of a yellowish green color. The pith of the sick plants is often found rust-eaten, as it were, and parched. Early in the fall the plants turn yellow and perish. The few tubers found are of a bad flavor, soapy, and hardly eatable; leaving, when eaten, a feeling of scratching in the throat. The very skin of the tubers is different from that of the sound ones; its color being partly brown, partly of a pale yellow, or often with both colors blended.

Experience has shown that certain varieties of potatoes are more liable to this disease than others; that they are less exposed to it on mountains than in the level country; that the round and oblong red varieties are more readily attacked by it than the white ones; and that this disease is propagated by the seed-potatoes, and does not disappear before the fourth or fifth generation, even when the plants are well taken care of.

Rust.—Another disease, which is mentioned as occurring contemporaneously with the curl, is compared by Putsche with the *rust* of the grain. According to his description, small rubiginous spots appear on the leaves of the sick potato plants, and, spreading gradually further, cover finally the whole surface of the leaves. The perspiration of the leaves being impeded, the stems become parched and wither; or, where this latter does not take place, black nobs are developed in the tubers, which are harder and more stringy than the rest of their substance. The causes of this disease are unknown; it is often but of short duration, and is cured by a gentle rain.

Mr. Hampe mentions a disease of the potato under the same name of rust, where the tubers show spots of the colors of the rust, with excoriations here and there. This disease occurred in cold, wet summers, when fresh dung had been brought upon the soil.

Blue pox.—Another disease, called *blue pox*, or *blue tumor*, not yet ob-

served by Mr. Martius himself, has appeared in several parts of the kingdom of Saxony, and in the Upper Harz. According to Mr. Hampe's description, blue spots and risings are first observed on the skin of the tubers; afterwards a dark colored texture, similar to a rhizomorpha, (probably the forerunner of a mushroom,) appears, which surrounds the tuber, penetrating even its interior, followed by blue spots and streaks in the heart of its substance.

It is said to be produced by an improper admixture of sawdust and pine-straw, and other imperfectly decomposed organic substances, with the dung. Very wet weather causes, then, the final outbreak of the disease.

Rot.—The disease which has lately committed so great ravages in the potato crops seems to be the same that was described first in 1769, by Gleditsch, and may be called the *rot*. In Germany it has been called "rot of the stem," "fruit cancer," "rot, or gangrene of the tuber." This same disease seems to have prevailed in the Saxon Voigtland, in 1783, when the summer was very hot and very foggy. It was described in 1784, by Dr. Ackermann. In the present century it began to show itself first epidemically in 1830, in France and Germany—in the latter country, in Rhenish Bavaria, Northern Bohemia, Saxon Mountains, Erfurt, Anhalt, Silesia and Meklenburg—and continued increasing in intensity, and spreading more and more, until it reached its height in 1840.

The *rot* may be designated by the dry and the moist rot, according to the degree of moisture either contained in the tuber, or acting from without upon it. Symptoms of this disease are—the potatoes brought home to the cellar, and the seed potatoes when laid on the field, get rapidly rotten; and the latter either rot before the leaves have sprouted, or they produce but small and scanty lateral tubers, closely attached to the seed potatoes, of the size of musket-bullets, which produce but very slender stems, or the plants that are grown from them are but meagre and soon droop and wither. At any rate, but few small and weak tubers are produced. These, when but little exposed to moisture, appear dry and hard, of a consistency like that of truffles, and unable to produce any eyes; when brought into the ground, they soon rot by attracting the moisture from the ground. Fields that suffer much from this disease look like stubble fields, where potatoes, left here and there, from last harvest, have sprouted. The flowers show themselves very unequally on such plants, and but very seldom produce fruit.

The rot seems to have appeared principally in those parts of Germany where a denser and more industrious population cultivate the potato in a more rational, but also more refined way, and chiefly where they raise their potatoes not by laying whole tubers, but by cutting these into several slices.

Too great economy in planting the potato seems, therefore, to have an essential influence on producing this epidemical disease. The two forms of mushrooms that are observed most frequently in potatoes attacked by the rot, are set by Martius under the genus *Fusisporium*, and are called by him *Fsp. Solani*, and *Fsp. sporotrichoides.*

Chemical analysis.—Dr. Andr. Buchner, jr., found, on a chemical analysis of potatoes infected with the rot, which he made at the request of Dr. Martius, that no new substance had been formed in them; they contained a considerable quantity of amylum in cases where the moist rot had not shown itself, but only the dry one—and its quality was not altered, but the albumen had disappeared entirely; and the quantity of water, of

which the sound potatoes contained 73.6 per cent., had been reduced in the diseased ones to less than the half; i. e., to 35.6 per cent. The fibrin in them was of a brownish color, and in part already mouldy.

Scab.—There appears often at the same time with the rot, another disease, less injurious, called the *scab*, which occurs, however, also sporadically, from a great variety of external causes. As far as it is known to Martius, the scab produces but very rarely an entire alteration of the substance of the seed potatoes. It is distinguished from the rot by its being merely a corruption of the cellular tissue, that lies immediately under the epidermis, followed by the generation of a mushroom, called by him *Protomyces tuberum Solani*, and by the destruction of the epidermis. The rot, on the contrary, infects the entire substance of the potato, and is an induration and a mouldiness of the tuber. Sometimes, also, the tuber that are attacked by the scab pass into a state of putrefaction, or produce but feeble stems, with fewer tubers, yet far less frequently than those attacked by the rot. Dr. Martius has not been able to determine whether the scab and the rot occur together on one and the same field, or even on one and the same plant.

Causes of the rot.—There are both external and internal causes of the rot, of which the former regard, first, the preparation of the seed potatoes for laying, and the soil wherein to plant them; second, the state of the weather; and, third, insects wounding the plants. The internal or predisposing causes regard, first, the peculiarities of the different sorts of potatoes; second, the manner of treating the plant on the field, and of treating the seed potatoes from harvest time to the time of planting them; and, third, the way of laying the tubers, and of treating the plant till its maturity.

Soil.—The chemical composition and the degree of density of the soil seem to have the greatest influence on the growth of the potato. In its native country, in Peru and Chili, it grows in cold mountain regions, and in a stony soil, that is rich in loam, but sufficiently loose. In Europe the sandy soil has been found the most convenient. The rot has been observed, however, on all kinds of soil, comparatively speaking; however, less frequently on a light, sandy, loose soil, rich in mould, than on a hard and heavy one. The scab of the potato, on the other hand, has been observed principally on lime soil. It is not so much, however, the original quality of the soil, as the particular way of preparing it, which seems to influence the rot, since it has been observed even on fields that were manured carefully, at the right time and with old dung, whilst other fields, badly cultivated or not manured at all, remained free from it, and yielded even good crops.

Manure.—Most injurious seems to be the bringing the seed potatoes in immediate contact with the dung. Manure is best applied before the beginning of the winter season. Dung that is too fresh and too hot is in general injurious.

Moisture.—With regard to moisture, stationary wetness is undoubtedly injurious. In its native country the potato is found thriving in a dry soil, which at certain seasons is strongly penetrated by moisture.

A rotation of crops appropriate to the locality has been observed to be favorable to the productiveness of the potato.

Weather.—With regard to the weather, as an external cause of the rot, we may conclude from all the reports that have come in, that most parts of Germany that have been ravaged by this epidemic have rather suffered by too great dryness, than by too great moisture. A long continuance of dry weather in spring proved very injurious to the sprouting of the seed pota-

toes in the Palatinate. On the lower Rhine, on the contrary, wetness was found to favor the breaking out of the rot; the same has been the case in the Harz mountains, and in Bohemia.

A very singular fact, observed in several villages of the Palatinate, was that of potatoes, taken from one and the same cellar; all those laid in the morning sprouted, while all those laid in the afternoon failed.

Martius is opposed to the opinion of those who seek the cause of the rot in insects laying their eggs on the potatoes, as but very rarely any eggs have been found on them. He is, on the other hand, not disinclined to side with those agriculturists who believe that two different sorts of potatoes of very different degress of acclimation being planted aside of each other, the one less acclimated will exert an injurious influence upon the other. In the year 1781, already several farmers ascribed the cause of the curl to the cultivation of the lately introduced *large American* or *New England hog potato*, the same probably as the *English cluster*, or perhaps also to that of the kindred *Howard*, or *large cattle potato*, in the neighborhood of the *red potato* then generally cultivated.

Internal causes.—Martius has observed the rot attacking only the late sorts. In the Palatinate, the *gelbe* and *weisse Speise-Kartoffel*, i. e. yellow and white table potato; and among these, more those of a softer and proportionally more juicy texture were chiefly attacked. In Saxony, Meklenburg, and elsewhere, again, all sorts were attacked indifferently.

Points to be observed in the cultivation of the potato.—In cultivating the potato, we have to attend to the following points, when we wish to obtain a healthy crop.

1st. The seed potatoes are to be raised separately from those destined for food, since the growth of the eyes in the tubers takes place at the expense of the amylum contained in them. In gathering and bringing home the potatoes, they ought to be guarded from all unnecessary concussions.

2d. In preserving them in cellars, they are to be kept from freezing, but so as not to prevent a free draught of air, since they begin to perspire soon after being brought in, chiefly in confined places, and continue to do so for four to six weeks; which perspiration, when not allowed to evaporate, occasions their decomposition.

3d. Those tubers will prove the best for raising vigorous plants whose eyes are yet quite short, but juicy, and where the tubers have just begun to spend a part of their nutritive matter in the formation of the eyes, which is recognised by a slight withering of them.

4th. Great care is necessary in propagating the potato by cuttings, as those whose eyes were wounded have been found particularly liable to the rot. Chiefly the upper part of the tuber, lying opposite to its point of connexion with the plant, and having the greatest number of eyes, ought to be used for planting. The cuttings ought to be kept for eight days at a moderately warm place before planting them, or to be strewn with wood-ashes or gypsum on the cut surface, in order to make them less accessible to the moisture of the soil.

5th. In laying the cuttings, care must be had to lay them with their eyes upwards. When, instead of entire tubers, cuttings only are laid, it is important whether the earth around them lies loosely or closely, and in what manner the ploughing is done. The rot has been in general less frequently observed where, instead of the plough, the spade is used. With regard to

the manure, Martius thinks it is best to cover the cuttings with earth, and then first to spread the dung over them in the furrows.

In the ore mountains of Saxony, the farmers have improved their potato crops in quantity, as well as in quality, by laying whole tubers, instead of cuttings, and preparing for every one of them a couch, as it were, of a handful of dried leaves, or of chopped straw, and covering them afterwards with earth.

6th. It is necessary to heap up the earth around the stem of the potato plants, and it will depend on the quality of the soil, and the sort of potato used, to what height that is to be done.

7th. It is injurious to the growth of the tubers to cut off the leaves and to pluck off the flowers; the later the season is at which the leaves are out, the more the future crop is diminished, as the plant will spend part of the substance accumulated in the tuber in forming new sprouts.

Rot a contagious epidemic.—Martius considers the rot of the potato as an epidemical disease, being contagious under certain dispositions, and having its seat in the tuber, in which it produces a peculiar decomposition and destruction of its form, which, at a certain stage of the disease, renders it unfit for self-preservation and propagation, and terminates with the production of a peculiar mushroom—*Fusisporium Solani.* Martius ascribes to the seed grains, or *sporules* of the latter, the capacity of infecting other tubers already predisposed to this disease, so as to produce in them the rot.

Fries, in his *Systema Micologicum*, and Unger, think the rot, as well as the ergot in the grain, to be produced by cosmic causes, and not to be contagious at all. Sinclair, Link, and De Candolle, on the other hand, think it contagious, and the last mentioned scholar believes that the seed grains of the smut (*uredo*) come always from below, out of the ground, in which they lie in great numbers, into the plants which inhale them, together with the water through their radicles. This opinion corresponds with the previous observations of Knight, Tillet, and Tessier.

The *smut* can then only develope itself when a diseased mixture of the juices has been prepared by unfavorable terrestrial and cosmical relations; as too fresh manure, sudden changes from cold to heat; or, *vice versa*, great wetness, too early harvesting.

Experiments have been made concerning the contagiousness of the *Fusisporium Solani.* When its seed grains were sown upon slices of both diseased and healthy potatoes, the mushrooms developed themselves very rapidly within three weeks. When they were sown on the outside of a healthy thin-skinned potato, its epidermis became diseased, which might be seen by numerous round dry spots of one twenty-fourth of an inch in diameter, and of a darker color.

Preventive remedies.—Martius does not expect to see the rot cease entirely. In order to prevent contagion, the ground of places where infected potatoes have been kept is to be strewn with pure dry sand or ashes, and in cases of strong infection, straw might be burned in the cellar, or the walls be whitewashed. The diseased potatoes themselves are not to be thrown upon the dunghill, but into the water, or to be buried. Seed potatoes that come from fields infected with the rot, before laying them, are to be slightly moistened, to be strewn with powdered lime and ashes, and to be turned with a shovel. Tubers that have not sprouted may be laid for some hours in lime water.

The only remedy against the seed grains of the mushroom buried in the

ground, is to raise in such a field, as long as possible, other fruits, and, when about to raise again potatoes in it, to mix the soil with gypsum, loam, lime, &c. *Preservatives* are: to select, for raising, some good sort; to separate the seed potatoes, from the very first, from those destined for food; to sort the potatoes according to their size; to reject those apparently healthy, that show discolored roundish tumors.

To secure the potatoes in the cellar from rot and scab, the cellar ought to be dry, and, if possible, laid out with dry boards, and ought to have a sufficient draught of air; the floor to be strewn, besides, to the depth of some inches with sand mixed with ashes, coal dust, or fine iron filings. The potatoes ought to be well dried before laying them upon this, in heaps of more than four feet high. Horizontal poles ought to be stuck in, with dry brushwood round, to draw off the vapors arising from them, and the potatoes to be laid upon the poles.

Extracted and translated by

HENRY SCHOLL.

ON THE DISEASES OF POTATOES.

Extracted principally from Die Kartoffel.—Epidemic.—Dr. Von Martius, Munich, 1842.

From the Gardeners' Chronicle and Agricultural Gazette, Sept. 13 and 27, 1845.

It is not a matter of surprise that a plant cultivated under such various circumstances as potatoes should be subject to various diseases. Some of these have been more or less imperfectly described in the older agricultural works; but in the absence of all minute details, it is almost impossible to ascertain precisely what is meant. Indeed, before the improvements which have been made in microscopes within the last 10 or 15 years, it was scarcely possible to enter into some points in the diseases of plants, which are now comparatively easy.

The principal diseases which have been noticed in potatoes are the curl, the rust, the blue pock, the scab, and the dry rot. The disease of the present year is different from all of them. The three first have not at present been sufficiently observed. For an admirable account of the two latter, we are indebted to the zeal of the Bavarian government, and the scientific researches of Dr. Martius.

The *curl* is described in the "Hanover Magazine," page 1779, as follows: "Soon after their first appearance the shoots become curled, and make but little progress afterwards; sometimes, indeed, they disappear altogether. Some, however, remain nearly stationary, either not producing blossoms at all, or only very weak ones, which soon fall off and yield no seed. They produce no tubers, or only a few minute ones, which are strong and unfit for food. These, however, when set, do not always produce plants infected with the disease. It is said that at the base of the shoots, where they spring from the set, there is a hole, which the author attributes to the agency of some insect.

This disease was extremely prevalent in England towards the end of the eighteenth century, and prizes were offered for the discovery of some means of arresting its progress. It is probable, from some of the descrip-

tions that were published, that it was accompanied in some cases by rust and scab; but in what degree the diseases are connected, it is at present impossible to say.

Various causes were assigned by those who first observed it. At present, the more general opinion is, that it arises from the use of over-ripe tubers. A fuller description is given of the disease in the "Monograph of Potatoes," published by Putsche and Vertuch, at Weimar, in 1819.

The plants which are affected by this disease have an extremely meagre appearance. The stem is unbranched, brownish green, or mottled, and here and there sprinkled with rusty spots, which penetrate to the pith, so that it is not white but rust colored, or sometimes black. The upper surface of the leaves is not so smooth as usual, but rough, wrinkled, curled, or crumpled.

The leaves are far more sessile than usual, and are not of a uniform brownish or dark green, but spotted. The passages for circulation, imbibition, and respiration, are none of them in a healthy state. The pith is often discolored, or dried even in the young shoots. The starved plant often perishes early in autumn, when the tubers should be making the most rapid growth. These are scanty and tasteless, juicy, and almost unfit for food.

Even the color of the outer coat of the tubers is changed. The same tuber is in parts brown, in parts of a dirty yellow, and sometimes the two tints run into each other. Some sorts of potatoes are more subject to the disease than others. It is more prevalent in flat countries than in more elevated districts.

The second disease mentioned by Martius is rust; which, however, as is in the case of the curl, he has not himself had an opportunity of observing.

It is described in the Monograph, quoted as above, as allied to the rust of wheat. Rust colored spots appear upon the leaves, which are at first small, but gradually increase, and at length overrun the whole leaf. As the respiration of the leaves is in consequence impeded, the stems are thin, and at last wither. When, however, this does not take place, the flesh of the tubers is infested with black knots, which resemble ulcers, and are harder and more fibrous than the rest of the flesh. The cause of this disease is unknown. It is often only of short duration, and is ameliorated by mild rains, so that the produce is not much affected.

The nature of this disease is evidently very obscure. It is probably the same with that mentioned by Standinger, in the Isis of 1832, as occurring at Altona, in land highly manured with herrings. The peasants about Hamburg and Altona attributed the rust in wheat to the introduction of potatoes. Holland had the monopoly of potatoes, and supplied Hamburg, but at length they depended on a home supply; and potatoes being largely cultivated on highly manured land, in consequence of a rise in the price of wheat, they believe that their wheat became infected with rust.

There is great doubt as to its being really allied to the disease in corn which bears the same name.

The third disease is the *blue pock.* Martius has not himself observed it. Hampe describes it as first appearing under the form of blue spots, and elevations on the skin of the tubers. At a later period, dark rhizo-morpha-like threads (probably the mycelium of a fungus) invest the tubers, or even penetrate their substance. Blue spots and stripes at length appear in the flesh of the tubers, which are not eatable. It is said that it arises in very

wet weather from undecomposed matter, such as sawdust, (which in the infected districts is used extensively for floors, instead of stand,) being mixed with the dung.

The disease, to the examination of which the greater part of Martius's book is dedicated, (the dry rot,) makes its appearance on the tubers after they are stored in the pit or cellar, and when, in early summer, the sets are committed to the ground. In the latter case they perish before they have thrown out any shoots, or merely produce one or two minute tubers, which either do not produce shoots at all, or only such as are extremely weak and soon perish. If there is little moisture, the tubers become hard and dry; and as soon as the soil becomes wet, the greater part perish, so that the fields appear like fallow lands sprinkled with a few stray potatoes of the last year's crop. The disease is often accompanied by scab; which, however, is not so universally diffused through the infected districts as the dry rot, but is sporadic in its appearance, while the dry rot is a complete epidemic.

It was first observed in 1830; but it had increased in the year 1840 in various parts of Germany to such an extent as to cause very serious alarm, and even to threaten the total extinction, for a time, of the cultivation of potatoes. The potato pits, when opened, exhibited a greater or less degree of corruption, three parts out of four occasionally having become altogether useless; and of the residue, when planted, the greater part often failed entirely.

In the early stages of the disease, the use of the tubers was not found to be injurious to man or cattle. In the latter stages of growth, however, the decay is such as to make it quite impossible to use them.

The disease is very insidious in its progress. When the crop is harvested, there is little to attract the superficial eye. The surface of the tubers is rather dull and wrinkled, and then gradually exhibits little round, brownish spots, which soon become confluent. The surface then appears more than usually cracked and reticulated, and at length scaly, the edges of the scales being free.

Sometimes, however, the tubers become transversely wrinkled, in which case their color remains nearly the same as in healthy individuals. Within, the tuber is clouded and discolored, and has an unpleasant smell, and is soon more or less impregnated with a peculiar species of mould, which forms white elevated compact spots on the outer surface, and is distinguished by its curved, fusiform, articulated spores. The grains of starch are found not to be in their normal state, their surface being covered with variously shaped processes.

This disease does not appear to have been sufficiently prevalent in this country to attract much notice. Whether it depends upon the growth of the mould, or whether the mould is merely subsequent to the disease, is uncertain. The mould itself is either very variable, or two or three species of a very similar habit occur on diseased tubers.

As, however, English and French specimens, though they exhibit a form of spores different from what Martius figures, present very material differences of form in the same tuft of mould, I am myself inclined to think that the different kinds may all be referred to one species.

The disease is often acccompanied by scab, which is easily recognised by its rather cup-shaped bordered pustules, the concave surface of which is covered with a stratum of large, more or less globular, somewhat reticulated spores, which are at first greenish, and at length acquire a ferruginous

tint. The spores are attacked at first by a little, somewhat lateral, thread, and usually exhibit a sort of hilum, which Martius has not noticed. They agree in structure with those of a parasite which is sometimes common at the base of a different species of Orobanche, and which has been described by Fries, under the name of Tuburcina. A similar fungus occurs on the leaves of Trentalis Europæ. Martius has referred it to the genus Protomyces, in consequence of not having observed the little thread by which it is attached. The scab occurs principally in ground which has been dressed with rubbish from old buildings, or where the soil is in a very raw and ill-drained condition. It is sometimes very destructive, and is usually to be met with in greater or less quantities in some portion of every crop.

Martius has entered into very minute detail, and at very considerable length, as regards both the dry rot and the scab, but we have stated sufficient to enable any one to recognise them. As in most cases of the diseases of plants, it is more easy to discover the cause than to suggest a remedy, the suggestions given by Martius are confined within a small compass. If the disease arise from the attack of a species of mould, it will, of course, be advisable to take all possible precautions against infection; though, where the spores are so subtle, this is almost a hopeless task. Some good, however, may be expected to result from change of soil, and proper purifying and disinfecting of the storehouses; and more, perhaps, from such a system of culture as will insure the vigorous but not exuberant growth of the crop. I have seen occasionally a good deal of damage among store potatoes, arising, I believe, from this disease; but, as I have not been able at present to obtain specimens of infected tubers from Germany, I cannot positively state that it is identical. The disease of the present year is altogether different from any that has been recorded.

M. J. B.

REPORT OF DR. VON MARTIUS, COMMISSIONER APPOINTED BY THE HIGH MINISTERIAL RESCRIPT OF AUGUST 25, FOR THE ACCURATE INVESTIGATION OF THE POTATO DISEASE IN THE PALATINATE.

[Translated from the Central Blatt des Landwirthschaftlichen Vereins in Bayern, by E. Goodrich Smith, of the Patent Office.]

To the Royal Academy of Science:

In executing the honorable commission of the 25th of August, to institute further investigations, in time and place, for the full understanding of the notices respecting the potato epidemic in the palatinate, for the examination of the locality, the local and general causes, and the more perfect judgment of the original cause generally, I visited, in the end of the month of September, the Land Commissariat at Frankenthal, and I now have the honor respectfully to report the results of my investigations in the following observations, prepared for the further use of the King's Minister of the Interior.

The potato crop of this year, in that region, has suffered a considerable loss. This is not of equal proportion in the particular fields; but while many farmers are satisfied with the product, both in quantity and quality, others in the neighborhood complain of a most decisive deficiency of stalks, i. e.

a failure of more or less stalks, so that the sprouts producing the knobs are either wholly wanting or have put forth only a few small knobs, or none at all. In the first case we observe the rows of the potato hills on the field interrupted, and this is the case in different circumstances. Many times a single plant is missed from the row; many times a whole succession of three, four, six, and more plants. In many this deficiency is scattered about in the same proportion; in others, on part of the field, all remain sound, while still another presents abundant marks of failure. Neighboring fields are often thus uninjured by the disease.*

The dissimilarity of this year's harvest, soil, and climate, being the same, confirms the view already presented—*that the proximate causes of the disease are not to be sought so much in these general circumstances as in local means of injury.*

The failure the present year does not exhibit itself, in the Land Commissariat of Frankenthal, so much in the early potatoes as in the much larger proportion of late patatoes. In the fields which for the most part I have investigated in company with the royal land commissioner, Von Pollnitz, there were everywhere round, middle-sized, white, yellow, or fine-skinned, mealy, clear, reddish kinds of potatoes.

At the first view of the fields in that region planted with potatoes, the circumstance was striking, that, although the stalk in the average had reached the usual development, yet the number of stems which blossomed or bore fruit was very small in proportion. While, heretofore, in Germany, in most regions, the potato stalks have been seen in blossom from the second half of August, and even the present year in many places—for example, on the Maas, in Mannheim, and Heidelberg—(in September numerous stalks were in blossom, and others bearing fruit;) yet in the Land Commissariat of Frankenthal, at the end of September the fields showed but very rarely a blossoming stalk, and the potato balls were few.

But otherwise, *in general*, on those fields which have suffered a loss of plants no visible change with respect to the stalk was to be noticed. Such had, yet further, the usual height and quantity of leaves, and only in particular cases, of which we shall directly speak, did any variation appear in those portions above ground.

A closer comparison of the particular plants on one and the same field showed *a great dissimilarity in the vegetation, as well in regard to the stalk as the knobs.*

---

* This view is confirmed by the different accounts of the disease in Germany, as well as in the ample statement which a Scotch farmer (Charles Ferguson) has collected together from the numerous notices of British agriculturists, inserted in the Journal of the Highland Agricultural Society at Edinburgh. The rot of the stem, in English, taint, failure, rot, dry rot, which made its appearance in an alarming manner in Great Britain, in 1834, as did the epidemic curl disease in 1792, has given occasion to many similar treatises. Ferguson has given prominence especially to—1st, the period of planting the knobs; 2d, the time when the knobs which had set were taken from the ground; 3d, the method of their preservation; 4th, the mode of preparing the potato fields; 5th, the kind and condition of the manure; 6th, the condition of the setting knobs; from what place they were taken; whether they were laid whole or cut in pieces; 7th, the question whether the plants were exhausted, and a renewal of the seed would be necessary.

The views of the British agriculturists are very diverse. But in one point they all agree—that cuttings warrant no surer crop. The general valuable results of the observations alluded to have been employed in drawing up the rules recommended at the close of this report. (*See report on the failure of the potato crop, in the Quarterly Journal of Agriculture of the Highland and Agricultural Society of Scotland, No.* 36, 1837, *page* 477—511.)

According to the results of such a classification of the different circumstances, bringing under view the whole growth, the plants which were found in the fields may be arranged in the following three groups:

Different conditions of the potato plant.

1. *Sound plants*, in which neither the part above or below the soil presents a diseased appearance. In general, these bear no very numerous product. The knobs, also, were not particularly large; an appearance which may be explained by the unfavorable circumstance of the long continued drought of the present year. The agriculturists of the communities visited by me, from the results of such sound plants, look for a moderate crop, or three-fifths of a good one.

Besides, in such plants is to be noted, also, that in small portions of the same the stalk was wholly withered by the 25th of September. Of the remainder, the conclusion was, that they would not be either high or branching; and corresponding to this, the knobs were not very large, but often under middle size; but the plants, which yet stood fully leaved, were provided with more and greater knobs.

2. A second portion of the plants, and indeed the smallest, showed numerous stalks; but these were thinner and more slender, mostly single or slightly branched, yet with many leaves. The leaves frequently bore more leaflets than usual; and these latter were often very small—only a fifth of an inch in diameter. The angles of the stalk were sometimes furnished with a proportionally very broad strip of leafy substance, and this more or less curled. Both sides of the leaves were more than usually set with very fine hairs, which gave the stalk a brownish-green appearance. On the leaves of this kind were also noticed, sometimes, black, burnt, dry places, yet without meeting any rust fully developed. The stalk also showed, many times, black spots. On plants of this description I have met with no blossoms or fruit. The root-stalk presented an unusually large branching, and the branch roots terminated in great quantity of fine fibres. The collective undergrowth appeared accordingly, as it were, an irregular felting of fibres, between which appeared only rarely one or a few knobs of one half to one inch in diameter. On the contrary, the lowest part of the stalk, where it passes into its branching under the soil without bearing knobs, and in the latter itself, which were often disproportionately long, were set with small knobs of pale color, and having a very tender outer skin, of the size of peas, and mostly furnished with leaf buds on their ends.

I hesitate not to explain the above described plants as infected with the before mentioned curl disease, (in French, *la frisole*,) though in a far less degree. But other plants appear smitten with the same disease on the growth above ground, of which nothing abnormal can be noticed, while the knobs exhibit a peculiar variety. Such knobs, indeed, bear long white sprouts, which put forth sometimes singly, sometimes numerous, on every part of the upper surface, and often are so-long that they run out of the ground, where, when they come to the light, they unfold many small greenish-gray, strongly haired leaves, similar to those in the curl disease. Many times this sprouting forth appears as a true, thorough growth, while the uppermost eye of the knob passes out from the so called "crown," over into a new green stalk provided with leaves.

Potatoes which were from plants of this sort exhibited often a variety of

appearance, which can only be distinguished by the experienced, reflecting agriculturist as sickly, and not to be used by them in the next planting for seed. They are usually below the regular size; often not round, but of a distorted, roundish form. Their outer skin is sometimes very tender, and sometimes proportionally furnished with little excresences, and allow the cellular tissue to shine through with a light, greenish clouding. On being cut into, they present a less compact texture, and also offer proportionally less resistance to the knife. The year-ring (Jahr-ring) exhibits a comparatively darker color; and where it breaks out on the outer surface, for the commencement of new eyes, it is often of a brownish color, and encircled by a clear, white, juiceless (nappy) cellular texture. Others, (still of these diseased knobs,) on being cut into, showed themselves to be what we, in common parlance, are wont to call *whetstony; i. e.*, considerable portions were juiceless, swelled up, filled with air. Such potatoes, in essentials, therefore, present the same peculiarities which we find in those which have begun to germinate in the cellar. When boiled, these knobs were tasteless, flat, or disagreeable, and of a fatty substance; and where they had passed over into irregular sproutings, or at least had diseased eyes, they showed the well known, uneatable chits, which are nothing else than the corrupted beginnings of the sprout (the germ-tuber) contained within the substance of the potato.

3. Besides these two already described kinds of condition of plants, there was exhibited yet a third, which has been distinguished by many agriculturists as *the first state of the prevailing disease.* In the plant usually no variation was to be noticed; it appeared much more juicy and leafy, and only sometimes an uncommon quantity of dark-green compact leaves, and the want of blossoms and fruit indicated a deterioration in the knobs. Still, one could not with certainty form a conclusion from the appearance of the plant as to the diseased condition of the knobs; and this diseased tendency first developed itself by the deprivation of the root-stand, which, according to the opinion of agriculturists, is connected with the "loss of the stalks" and the "dry rot." These potatoes have the following characteristics:

(*a*) In one case, there were numerous knobs; but these were small, (not full grown,) provided with a very thin clear-colored outer skin, and many times also somewhat greenish. The upper surface had many little warts, rents, or dark-colored places, with reddish brown spots, like spots of rust. Such half-grown knobs were of a peculiar dried up appearance, and thus less smooth and shining than sound knobs. In some cases, also, the outer skin was wanting in certain small spots, and a white eruption, which dropped off easily, consisting of grains of amylum, took the place of the outer skin; sometimes even these knobs (plainly not yet ripened) already had put forth short sprouts or shoots.

(*b*) In the other case, the stalks, when taken out of the ground, were found to have a moderate amount of knob formation, and the knobs were tolerably large and grown out. But they bore immediately on their surface sometimes one, sometimes more, bunch knobs of the size of a marble, musket ball, or nut. This after-growth, which, according to the opinion of the farmers, owed its existence to a late rain, after a very long drought, is for the most part found on potatoes which exhibit a broken, and here and there dark-colored or light brown, somewhat dry upper surface. The mother knobs, also, on which they sit, have, not rarely, a variation of form,

while in an angular transition-form from the ball-form to that of an irregular ragged body. The bunch knobs themselves are covered with a thinner, often reddish, swollen, outer skin, and not unfrequently bear a cluster of young prematurely-developed eyes.

On the knobs thus changed by disease being cut through, it is noticed that the vascular circle which pervades the whole texture of the knob, and distinguishes the outward (the rind) from the inner part, (the marrow,) is colored darker (yellowish) than usual; but the cellular tissue which lies inside of the vascular ring is softer than the part which lies outside of the same. Such a potato offers less resistance to the knife cutting in than does a sound one; and sometimes little holes are found already to exist in the inside. The inside also differs in color, since it is rather of a milk or slimy white, than of the otherwise prevailing color—yellowish-white, or slightly changing into red. These peculiarities are so visible that many agriculturists regard them as the certain signs of the introduction of the disease. They are wont to call such potatoes, very appropriately, *glassy*—which expression is at other times used respecting those which, being frost bitten, have begun to sprout in the cellar.

If the potatoes described under *a* and *b* are cooked, the substance exhibits the same slimy or fatty state, and the same want of palatable taste which is found in potatoes which have sprouted. In large plants we often also find that the outer part (outside of the year ring) is yet mealy and palatable, whilst the inside has already undergone a slight decomposition, and is stale and harsh. Many times, also, such a potato cooks very differently: some portions remain harder than others, and the rind part, which is still tolerably mealy, crumbles before it is prepared. It is this state which is called by many "the double growth" or "offset." Very often such a dressed potato presents on the cut surface immediately a light violet color, which indicates that some *tannin* has been developed in it—a change which must naturally also make itself known by the taste.

Influence of the premature development of the sprout on the taste and the inner structure of the potato.

It may be appropriate here to notice how this change in the taste of the potato is connected with the untimely commencement and progress of growth and development of the near sprouts. When, indeed, a mother potato begins to sprout, it first takes place in the portion of the cellular texture lying in its centre—the marrow for the after growth. From this the young shoot is nourished, which receives its vessels from the year-ring, and by means of the same stands in the closest connexion with the marrow portion. The nourishment goes on, while, from the centre, the amylum is converted into diastase and sugar, the sugar into slime, the slime into fibrous substance and albumen, and from the last the cellular tissue of the new sprout is formed. In a sound case, the mother potato accordingly is gradually, and in due time, hollowed out from the middle. If it is very large, the sprout growing forth already obtains a considerable development before that is wholly exhausted; in which case it is hollowed out, but near the circumference it remains still solid.

There remains, therefore, in a wholly regular process of nutrition at the end, only the shell, dried up and hanging on the new-formed stem. Where, on the contrary, we observe the mother knob not thus regularly

employed for the nutriment of its offspring, but wholly or partially becoming rotten, there it is supposed that the part which furnishes nutriment to the young sprout has not had a regular but diseased course. The too early, *over-hasty* putting out of the young knobs, as presented in the cases described, is connected with a diseased tendency of the mother knobs, *which does not check, but too much hastens, the usual periodicity in their production*, in consequence of which the decomposition of the cellular tissue must become putrefaction; which I have met with, in all such cases, in place of the regular exhaustion, even to the skin.

State of the present crop in general.

If we lay the already stated circumstances together as they have been observed in the open field, in the Land Commissariat of Frankenthal, we shall arrive at the following general result:

The vegetation of the potato plant appears in the *highest* degree. The whole progress of its growth, even in kinds planted under similar conditions of soil, climate, and culture, and in the same region, is *very different.*

The *stalk part* is partially retarded in its development, so far as the observation in general could be ascertained, so that it came to the blossom more seldom and more various than for some years.

The *knobs* did not ripen equally in a short period, but took a more gradual succession.

The *quantity* of the most domesticated potatoes is only a middle crop or below a half crop.

The *quality* in not an inconsiderable portion of the crop exhibits itself already as small, indeed inferior, inasmuch as these potatoes have no good taste. Their present condition renders it probable that they will not preserve long in the cellar.

I must here also add, that the peculiar irregularities which we have already mentioned have been found in different kinds, and as well in those potatoes which were grown from entire potatoes planted as in those from cuttings.

A part of the potatoes are already diseased, or have such a tendency in the field.

From the above mentioned facts we may very justly conclude that a part of this year's crop of potatoes were not wholly sound, *but already disposed to disease, or really diseased, in the field.* But as now experienced farmers in these peculiarities which are exhibited in such diseased potatoes *recognise the first symptoms of the dry rot*, it hence follows *that the dry rot did not originate first over winter in knobs before wholly sound*, but that the *foundation* or *germ* of the disease *was transmitted from the field with the potato into the place of preservation*, and that consequently *the disease fully developed*, namely, the remarkable hardening and the appearance of peculiar fungus in the upper surface, *was produced where the circumstances prevailed to favor such a development in the primary source of the disease.*

The disease is connected with the fungus as the primary source or origin.

For the scientific stand-point of the investigation, the question now especially is important, whether this disease consists merely in a peculiar de-

struction of the vital power, and in a corresponding decomposition; or, whether, according to the conclusions of my earlier investigation, the germ of a parasitic fungus already exists in the potato on the field, in which case it must be recognised as the original cause of the disease.

The investigations which I have instituted on this year's potatoes, on the field itself, confirm the last opinion most fully, as I have found the germ of the fungus also in such knobs.

We may observe, indeed, without trouble, and with the eye simply, the potatoes described under letters *a* and *b* (which were distinguished by experienced agriculturists as the first stage of the dry rot,)—fine, white, little points here and there scattered beneath the outer skin; these, through the clearer color, distinguish themselves before the rest of the cellular tissue, and give it the appearance as if little grains of meal were enclosed or sprinkled on it. On closer examination, it is found that these little white points, as it were, in nests, i. e. united in small round or oblong spots, lie in the cellular tissue. They are found especially in the outer portions of the tissue, between the year-ring and the outer skin. Slightly magnified, they appear as irregular shaped, yet for the most part rounded, opake, white, shining grains; when strongly magnified, they exhibit themselves as a slime. But after being yet stronger magnified, from three hundred to four hundred lines, we can detect in these little invisible points an uncommonly fine tress-work of wreathed, ramified, half opake, here and there dismembered fibres, wholly like those which I have acknowledged, from the cases of disease before more fully described by me, as a fungus texture of the *Fusisporium*, and represented in table 3, figure 23, of my treatise. Here and there, also, are seen in the cellular tissue those disproportioned, globular, and for a time still half opake, pale yellow little bodies, which are the commencement of the original fungus, *(Protomyces Solani,)* and represented in table 3, figure 21, of my treatise.

In other knobs, even when first taken out of the ground, I noticed, as mentioned above, that here and there little portions of the flesh broke through the outer skin in the form of irregular clusters of small white grains. By the miscroscope they were proved to be grains of amylin, on which little excrescences and bands had begun to form, which I have represented in table 3, figure 34, and have distinguished as the earliest organization of single fungus fibres.

The last appearance also observed in knobs artificially infected.

This appearance wholly agrees with that which some before sound potatoes presented to my view, which were artificially covered with fungus dust, and which were also thus inoculated. The outer skin of the same first showed rotten, brownish, dry spots, by which the whole knobs plainly lost in moisture; three months after, the infection broke out of the outer skin here and there, and the diseased cellular texture pressed through in the form of little white bunches of meal, the grains of amylin of which at the same time, attended with small excrescences, callosities, and bands, might be recognised as the medium of the fungus texture in its earliest period. In sound potatoes, the starch meal never shows the above described beginning.

The germ of the fungus texture already existed on the field, and became developed in the most unfavorable circumstances.

The experiments hitherto made by many investigators of nature have placed it beyond doubt that the first germ of a fungus texture may remain for a long time in its primary, incomplete state, without losing its vital power; but that, in circumstances which favor its perfect and entire growth, it always more and more developes itself, increases in size and extent, and finally reaches the state of ripened fruit, where it then puts forth numerous germs as grains, and thereby accomplishes its propagation. *On such a growth of fungus texture, the moist, warm weather has the most important influence.* No fungus grows in a temperature below 2° or 3° of Reaumur. For, on the contrary, a high temperature up to 15, 20, or more degrees is very favorable to its development, of which any one may be convinced by the common mushroom of the sewer and of the marshy beds of botanic gardens, which are well known to be often covered by the vegetation of the *Aethalicum flavum.* It follows, therefore, that potatoes in which the germ of the fungus already exists undergo the progressive deterioration even to the highest stage of the dry rot, not in all places, but only where they have been surrounded with a damp atmosphere, and have been shut out from the light, while in the winter and spring a considerable temperature is developed.

The inquiries which I have instituted in the Land Commissariat of Frankenthal, as to the condition of the place where sound or diseased potatoes have been preserved, confirm this opinion.

A great landholder in Petersau, who was accustomed not to bring in his stock of potatoes into cellars beneath the ground, but in parts, of slight depth, of a large barn furnished with dry walls, has not yet suffered from the dry rot; on the contrary, we find that agriculturists, whose crops have been injured, have been accustomed to fill in their moist dark cellars, shut out from the draught of air, wholly with knob-fruit, where is also a heating, and with this the essential condition for the formation and greater development of the fungus texture, and consequently of the higher stage of the dry rot, which hardens the potato, and renders it wholly unfit to be eaten. Many weighty authorities have lately represented this heating as the *sole original cause* of the dreaded disease. On the contrary, I consider myself justified in setting it down as only *an essential condition of the last form of the dry rot.* Without the peculiar co-operation of the fungus forming itself out on the heated potato, the knob fruit might wholly lose its power of germination and good taste; but it cannot escape the view, how the fruit, also, may in itself thus present that peculiar and so greatly diverse character of *a sort of fungus hardness, with a contemporaneous production of a mouldy fungus on the upper surface,* and, indeed, always of one and the same sort, when the fungus does not thereby perform a definite part. By the heating, in the cellar, the potato suffers a commencing decomposition; a part of the starch turns into sugar; and then, by means of the processes of germination, as they begin, into stringy substance. From this it goes (if hindered in the proper development of its shoot) over into the *wet* rot. The quantity of water in it will hereby, indeed, be hardly as much lessened, as is the case in the dry rot where the knobs lose half of their watery substance. That, on the other hand, the potato contains the same peculiarity by means of which it resists the operation of the water in which it is cooked, and, indeed, also the steam of water; and after it has been cooked for six hours, so that it can only be cut with a very sharp knife, as a

moist spunk—this circumstance is merely the consequence of the fungus development.*

Contradictory, also, as this fact must appear at first view—that a tender, mouldy fungus may exert this drying up, hardening influence, rendering it tough on the substance of the potato—yet it stands not isolated, but is well known as analogous to the effects of other fungi. The sepedonium mycophilum, a little yellow filamentous fungus, which grows on flesh-colored mushrooms, thickens the cellular tissue of this latter so much that while otherwise it rots in the last warm days of autumn, now affected by this parasite, it not seldom withstands putrefaction during the whole; and yet, in the spring of the next year, is found dead, indeed, but preserving its original form. In a similar manner, also, other fungi which grow on wood—as, for example, species of the warty mushrooms, thelephora, and the inflated mushrooms, as sphaeria—produce such a peculiar drying up and contraction of the wood, which draw out in the same manner its albumen, as does the fungus of the potato spoken of†.

Of the fungus found in potato cellars.

In the house of Burgomaster Von Heissheim, who, as an agriculturist, for many years has suffered much from the potato rot, I noticed that the walls of his moist, damp cellar were here and there covered by a very fine web of white filamentous fungus. The same extended itself, even as such vegetation otherwise is wont to do, out from a middle point to every side for some inches diameter. This covering was scratched off, and in Munich was subjected to a careful microscopic observation. It consists of very fine ramified complicated fibres, and it is probable that it is a mother fungus, slightly developed on account of its barren situation, and of the same kind of vegetable growth to which I have attributed so important an influence on the existence and formation of the dry rot. It may not be impossible that the close contact of the potatoes, stored up within the walls, with the fungus mould vegetating there, may have been the means of infection, and contributed to the appearance, inexplicable to the agriculturists, that one row of seed potatoes did not shoot forth, while another from the same cellar developed themselves regularly and in a healthy manner. Besides this, the occurrence of a mother fungus, not on the potato itself, but in other places, which group themselves under certain favorable circumstances in the same, and here are extended with much greater rapidity than elsewhere, may be considered as an appearance of which we find many analogies in nature, and it must be looked upon with reference to the inexplicable mode of the spreading of the disease, as if it was a contagious epidemic. It is thus with the increase of the dry rot, just as with the sudden appearance of certain destructive insects, which also are not newly generated, the eggs of which still more always exist, but only reach their development under favorable circumstances.

---

* Very justly says the intelligent agriculturist, Knight Von Kalina: "Although the heating of the potatoes during the winter preservation must unquestionably have promoted their rotting, yet the wholly peculiar disease distinguished by the name of dry rot cannot so be explained only. This heating must be followed by a fermentation and a wet (not a dry) rot, arising therefrom." (André Oekonomische Neuigkeiten und Verhandlungen, 1842, n. 69, p. 549.)

† Compare, as to this peculiar effect of cryptogamous parasite, *Treviranus* Physiologie der Gewächse, Band II, 792, in Bavaria, 1842, p. 443.

Microscopic discoveries in diseased potatoes which bear on them no fungus formation.

The potatoes mentioned under 2, exhibit under the microscope more or less extended variation from the regular formation. The appearance most visible in them is a deficiency of grains of starch in the cellular tissue. The same is the case also in those which are yet juicy throughout, but which are of a soapy or fatty state, as well as in those which are already become whetstony.

(*a*) Many cells contain, in these cases, scarcely any grains of starch. They are filled with liquid or air, and their skins are withered or flabby.

(*b*) In other cells the grains of starch are balled up together in the middle, in the form of round balls; or,

(*c*) They hang in clusters heaped up on the sides, especially in the corners near the intercellular passages.

(*d*) These last are not seldom wholly stopped up—that is, filled in with an opake, shiny mass, a shapeless clot.

(*e*) The vessels of the year-ring are of a darker color than usual. The same is the condition of the vessels which run from the year-ring outward, to the eyes in the so called germ-tubes. The texture near the last is often juiceless, and, as it were, standing off, (nappy.) Thus, as also the condition of the new sprout shows itself changed, diseased, at the earliest period, it cannot be thought strange if the same shoots out no new stalks, or retains only a very weak power of production.

All the above mentioned appearances are found more or less decisively in those seed potatoes which have already put forth sprouts, and in consequence have dissolved a portion of their texture and employed it for the development of new stalks. Thus with such knobs, already provided with sprouts, the change described shows itself always in the inward parts of the cellular tissue; *i. e.*, inside of the year-ring. These appearances, therefore, indicate that those potatoes which have become fatty, or whetstony—and which, on account of their less size, and of a weaker portion in the starch formation, are to be considered *as not yet ripened*—have begun with a sickly haste to develope their eyes. It is evident that their offspring must likewise be feeble.

Finally, I further notice that the scab or scurf was scarcely observed by me in this region, or with less intensity, while in Upper Bavaria it appeared to be spread about abundantly.*

Result.

From the comparison of the facts, and with respect to the location with which they are connected, the following general conclusion is drawn:

For the irregular vegetation of the potatoes (the deficiency of stock) observed in the Land Commissariats, and the rotting of the knobs in the cellars, two diseases, the curl disease and the dry rot, are original causes.

The curl disease, which appears hitherto to be developed in no high degree, depends on an irregular vegetation of stalk as well as of knob, on account of unfavorable circumstances of climate and soil and disproportional

*Some have accounted for this disease especially from the excess of protoxide of iron in the soil.

culture, whereby the knobs lose in their starch substance and imbibe a tendency to put forth untimely sprouts.

The stalk rot was *occasioned* by a nesting of the fungus texture in the knobs, which injures the chemical mixture, and so gains the upper hand in the knobs, by favor of a heating method of preservation, that this becomes unfit for germination, and, by means of the hardening of its cellular texture, can no more serve for nutriment. This disease also affects sound knobs as well as those which spring from curly stalks.

While the curl disease appears to have been for a long time known as an epidemic, but not infectious, that which for ten years has been known as the dry rot has at its foundation a concrete contagiousness.

Against the former, therefore, must be prescribed all those means which rational husbandry generally recommends; against the latter, likewise, a careful removal of contagion, and guarding from those circumstances which favor the spreading and development of the contagion.

Precautionary rules against these diseases.

Let there be a careful previous assorting of the potatoes harvested, and a choice made only of such knobs, for future planting, *as are sound and well ripened.*

For this purpose reject all knobs—

(*a*) Which have reddish, or brownish, or black spots, with cracks and splits of the outer skin; or,

(*b*) Such as are affected with knots, warts, or with any appearance of mould;

(*c*) Or on which are set other little tubers;

(*d*) Which have a thin upper skin, partly scraped off, or of a color turning to green;

(*e*) Which, by their smallness, or by the adherence of long pieces of stalk under the ground, show that they are not yet fully ripe;

(*f*) The form of which is angular, or remarkably irregular, varying from those of the well-formed kind;

(*g*) Which are withered, wrinkled, hard, or exhibit a diseased variation of the eyes;

(*h*) Which have been cut in or bitten, or otherwise wounded;

(*i*) Which have already begun too soon to sprout in the cellar. The practice of planting such potatoes, again deprived of their sprouts, is in every respect very faulty.

We should not employ a potato as a seed potato which on one side appears wholly sound, but which on the other bears on it any of the above mentioned traces of a diseased state; the assorting of the necessary seed potatoes (so far as such have not already been brought in separated) should be done in the day light, so as not to overlook the diseased state. We should choose, for preservation of seed potatoes, most suitable places, as far separated as possible, which are safe from moisture, cold, and heat.

Remember that seed potatoes piled up high, not only in winter but also in spring, when they begin to sprout, undergo a heating, and thus become injured in their power of germination; which, therefore, must be carefully provided against. Moreover, let there be an assorting of the great heaps of potatoes for use, by means of a grate or sieve, which will separate the knobs according to their size. Save out the large, well ripened knobs, separate

from the smaller and later, and use the latter, before the rot has affected them, earlier than the former.

Preserve also these collections with all possible care.

If the cellars are not clean, whitewash the walls and strew the bottom of the cellars with dry sand mixed with coal dust, ashes, or sifted cinders.

Take care as to the proper access of air; set poles perpendicular in the cellar, which are to be wrapped around with pea straw, and about which the potatoes are to be heaped up.

Turn over these heaps during the winter.

Improve the vital power of the potatoes to be cultivated, by those means which a rational method of agriculture, having respect to local circumstances, and those of climate generally, recommends.

Try to obtain and preserve an appropriate, strong stock, or race. This may be done by a selection of sound, strong, ripe seed potatoes from the kinds which agree with the location.*

Let there be prudence in the naturalization of a kind which has been formerly raised under very different influences. Cultivate the kinds separately, and not together.†

Choose the most favorable soil, the best situation, and the manure and rotation most appropriate for soil and climate.

Put the manure on the field before winter. In England, it is recommended to mix horse and cow dung; to withdraw the same from the direct rays of the sun, and plough it under in every case as long as possible before planting. Swine dung in Thuringia has operated unfavorably. Fail not in a careful preparation by cleaning out, loosening, and heaping up.

Avoid laying seed potatoes too early or too late, or in unfavorable weather. (Local experience must be principally relied on here.) ‡

Leave not the seed potatoes long uncovered in the furrows, and let not these last dry up too long in the sun.

Beware, lest the seed potatoes themselves, selected with care, should be attacked with fungus germination; and therefore soak them some hours in lime water, and after they are dried off again in the air put them in the field. This treatment destroys also any insects or their eggs which may be attached to them. Experiments made in the Royal Botanical Gardens, with laying in lime, have proved that potatoes which have lain ten hours in lime water have not lost their germinating power; which, indeed, was the case with such as had lain from 24 to 36 hours in lime water.

The method of laying cuttings instead of whole potatoes, should in no case be adopted in the present unfavorable circumstances; as, without

---

*To improve the stock by derivation from seed, I do not consider necessary. By such a method, in general, two years are lost; and in the third, there is yet the labor of separating and collecting experiments in favor of their employment in given situations, as to the various kinds which have been produced. Similar are the views of experienced agriculturists; as, for example, Professor Schweitzer, (Allg. Anzeig. d'Deutschen, 1841, No. 341–344.) We have the experience already (for example, of Mr. Albert, in Rosslau,) that the knobs from stocks which have been produced from the seed were also attacked by the dry rot. There is, therefore, in this method, in no way any protection against disease.

†The English farmers recommend, after some years, to import new seed potatoes from higher situated regions.

‡In general, it seems more advisable to put the potatoes into the soil too early than too late. The practice of laying them too late, even in June, has undoubtedly contributed to enfeeble many races.

doubt, it has exerted an influence in the deterioration of the race, and will exert the same in a higher degree.*

* Gather the crop not before it is ripe.

Throw not those potatoes which are affected with mould, or otherwise useless, on the dung hills, but into running water, or bury them in a place which will not be ploughed up.

The adoption of the above mentioned rules must essentially contribute to limit and gradually eradicate the diseases at present so injurious, and increasing in such a threatening manner.

DR. VON MARTIUS.

MUNICH, *November* 4, 1842.

---

*The agriculturist who will not break off from the practice above mentioned, as bad, should at least take care that only sound cuttings, well provided with eyes uninjured, should be planted, that they be not cut too long before placing, and that those cuttings be rejected which change visibly in color on the surface of the cut. The sprinkling over of the cut surface with powdered lime is recommended by many agriculturists as a proper improvement.

APPENDIX No. 7.

GRASSES FOR THE SOUTH.

Editor of the Cultivator: Your correspondents frequently inquire respecting the grasses suitable to the south. If each would communicate what he has observed, it would be a sufficient answer to such inquiries, and might prove the most important benefit to the agriculture of the south. During this winter I have seen bundles of *northern hay* brought to the stables of my neighbor, which had paid for carriage many hundred miles round the capes of Florida, through the gulf of Mexico, and five hundred miles (by the course of the river) into the interior. This is a *standing reproach* to the agriculture of the south.

Lucerne.—This is found to grow well here. Sow it in drills, in the early part of the fall, 24 to 27 inches apart: it flourishes, yields four to five cuttings in the course of the year; and, on soil which would bring twenty bushels of corn to the acre, grows one foot and a half high. This season, some was cut on the 12th of March, for soiling, and was then from a foot to knee high. The most of it has been cut twice over, since the first cutting to this day, May 13. Cattle and horses eat it greedily. A cow fed on it chiefly is yielding at this time between five and six gallons of milk daily; when, as yet, there is no grass in the woods or on the common sufficient to change the poverty-stricken appearance of the cattle in "the range." I have made no hay from it, but have no doubt it will make good hay.

Guinea-grass.—The root is similar to that of the cane or reed, and is perennial. The stem and blade are like those of the Egyptian millet. On rich soil it is very luxuriant, yielding many cuttings in the course of the year. It is good for soiling; horses and cattle eat it readily, and, if cut when in flower, it makes a hay most abundantly, of which cattle feed greedily in winter. Horses do not seem to like the hay. It is most readily propagated by the root. A small root, two inches long, with one or more joints to it, will vegetate; and, if the ground is made loose by ploughing once or twice during the season after planting, roots placed in checks of four feet will take *complete possession of the soil the first season*, so that the next spring it will start up evenly over the soil, everywhere. Hogs root after them with great eagerness; and as the tendency of this plant is to fill the ground with roots in so thick a mat that the grass does not grow tall in consequence, the idea suggests itself of pasturing cattle on this grass in the spring and summer, and giving the hogs the benefit of the roots in the winter. They cannot destroy it; the smallest fibre left in the ground will grow. It might be a great pest in a *garden;* but if land is to be used for stock, it will take and maintain entire possession, to the exclusion of any competitor which we have in middle Alabama.

Clover and herds-grass.—I have now a beautiful lot of these grasses in conjunction, on high land; the whole about knee high, and the clover in flower. Mr. Kirby, one of my neighbors, cut the wood from a piece of low, pipe-clay, crawfish land, last winter; and when the brush, &c., lying

on the ground, had become sufficiently dry, he set fire to it and burnt it all off; thus giving it a top dressing of ashes. He then sowed herds-grass on the top of the ground, without plough, harrow, or any thing of the kind. He now has a most rich and beautiful crop of this grass growing. If desired, your readers may obtain further particulars of this crop.

Leersia Orizoides, (rice grass.)—This plant so much resembles *rice*, that only a practised eye can distinguish it. The negroes on the rice plantations in Carolina call it "*the rice's cousin.*" It will grow wherever rice will—*in the water*, or in any damp situation. It is found wild in all the southern country; grows tall, seeds in a panicle, not unlike a head of oats, and will yield two crops a year of *choice hay*. Roots perennial.

B. M.

TUSCALOOSA, ALA., *May* 13, 1845.

From the Mark Lane Express.

GURNEYISM.

This term, of whose meaning perhaps nineteen-twentieths of our readers are utterly ignorant, is applied to a new and particular kind of manuring, which has been employed with signal success by Mr. Gurney, a farmer in East Cornwall. The operation consists in covering grass land with long straw, coarse hay, or other fibrous matter, about twenty pounds to the fall; allowing this covering to lie till the grass springs through it (which it does with astonishing rapidity) to the desired length, and then raking it off to allow the pestial to reach the pasture. The covering is then applied to another portion of the field; the operation of removal and covering being repeated so long as the straw or hay remains sufficiently entire to admit of convenient application. The merits of the system, which is yet in its infancy, was thus stated by Mr. Gurney at a late meeting of the East Cornwall Experimental Club: "About seven weeks since, he had covered half a field of grass of three acres in this manner, and about a fortnight ago, when examined, the increase had been found to be at the rate of 5,000 pounds per acre over the uncovered portion of the field. At that time the straw was raked off and laid in rows twelve feet apart on the field, and one hundred and fifteen sheep were put on the grass, with a view to eat it down as quickly as possible. After they had been there about a week they were succeeded by twenty-six bullocks, to eat off the long grass remaining, and which the sheep had left. The field was thus grazed as bare as possible. The same straw was now again thrown over the same portion of the field from which it had been raked; and, on inspection that morning, he had found the action going on as powerfully as on the former occasion. He thought the sheep, on first raking off the straw, were not so fond of the grass as they were of that uncovered; but after twenty-four hours' exposure to the sun and air, he thought they rather preferred it. He had forty acres now under the operation, and in consequence of it he had grass when his neighbors had none." Fibrous covering, or Gurneyism, as thus described, is certainly a cheap and convenient mode of manuring; all that is wanted is only further experiment to test its general applicability.

From the Cultivator.

CUTTING AND CURING HAY.

From our notes of the discussion on "the proper stage for cutting grasses, and the best modes of making hay," at the seventh agricultural meeting in this city, we give the following:

Mr. Bement said he had formerly been in the habit of cutting timothy grass quite late. It was easier cured after it got pretty ripe. But he found, in using hay thus cut, that it wanted substance, and he had ascertained that the best time for cutting was while the grass was in blossom. In making clover hay, he had adopted Judge Buel's plan. He thought it best not to expose it much to the sun. His practice was to cut in the morning, let it lay till noon, and then cock it, and let it sweat for two or three days, according to the state of the weather. On putting the hay in the barn, he had used about four quarts of salt to the ton. Hay thus managed came out in the spring very bright and sweet. In the ordinary way of curing clover hay, the best parts are wasted.

Mr. Howard was aware that there were different opinions as to the proper stage for cutting grass; but he thought the observance of certain principles might afford a guide in the case. For example, the stems of grasses were filled, just before the formation of the seed, with a starchy or saccharine substance. In perfecting the seed, the stems were exhausted of this substance, it being consumed in forming seed. Now, if the herbage is the object, the plant should be cut before the nutriment has passed from the stems. If seed is the object, the plant must, of course, be allowed to attain a good degree of maturity. Hay made from ripe grass may "go further," or "spend better," as the argument is; and it is admitted that this may be true, for animals are less inclined to eat it; but this is no proof that it is more nutritive. He spoke of the different modes of curing hay, with nearly all which he said he had been acquainted. Clover hay was altogether better when cured in cock than by any other mode he knew practised. All hay was better for undergoing, to some extent, a sweating in the cock. Coarse timothy was thus rendered much softer, and was less strawy and stiff, and every description of hay was less likely to be "mow-burned."

Mr. Betts was not in favor of mowing a great deal of grass while the dew is on. He was in the habit of spreading the swaths as soon as the ground was dry, and he always had it well cocked up before night. The next day, if the weather was good, he opened it again: if it did not dry enough, he put it together again; but his object was to get it so that it would do to put it in the barn. He was in favor of using a little salt with it. He had sometimes found his hay heat too much in the mow. From being hurried, he had occasionally put a load in the barn too green. To stop the heat and fermentation which had ensued in such cases, he had made holes in the hay with a crowbar, and scattered in salt. In this way he had stopped the fermentation, and saved his hay in very good order.

Mr. Garretson, of the assembly, from Dutchess county, said he generally cut from 150 to 200 tons of hay per year, chiefly timothy and red-top. He generally begun when the grass was in blossom. His method was to cut in the morning, spread the swaths lightly, and in the afternoon put it in cocks. The next day, if the sun came out, it was again spread, and, if made enough, put in the barn with a little salt sprinkled on it. About three quarts of salt to the ton was as much as he used. There was danger

of using too much. He had formerly used more salt, and was satisfied his animals, particularly sheep, had suffered by it. It occasioned scouring, and, by keeping their bowels out of order for some time, they died. He usually got about two tons of hay to the acre. In the latter part of the season, it would sometimes make enough in one day.

Mr. Mack always directed his men to make hay as rapidly as possible. He had often made it and put it in the barn in one day, and never had better hay. He was always particular to secure it from dew when it must be left over night. It is said by some who had much practice in making hay that it is never injured from its own internal juice, but only from rain or dew.

Mr. Sotham did not like the plan of salting hay, neither did he like the hay that was made in one day. If it could be so made that it would take no hurt in one day, it must have been too dry for good hay before it was cut, or else very light burden. He would as soon have good bright straw for cows or sheep as timothy hay after it had gone to seed. He cuts clover when a part of it is in blossom and part in the head; cuts all his grass early. It takes longer to make hay cut thus early; but for cows, and sheep especially, it was a great deal better. The objection to salting hay was, that animals were forced to eat salt, whether they wanted it or not, and it made sheep scour. His hay came out of the barn of a bright green color, and his stock would fatten on it. There was another great advantage in cutting early: the roots retained their life and strength better, and the after feed and future crops were much more abundant. He did not like timothy for hay; he never saw it in England; the farmers there thought it was too coarse and wiry for stock. Rye-grass made good hay; would yield in England two tons per acre. Pacey's was the best variety; red top made good hay. He had tried sainfoin; it did not come up well; there was always a difficulty about it in this respect, because the seed was good only a short time; it could hardly be brought across the ocean and vegetate. If we could get it here, it would be very valuable, especially for dry lands. As to pasturing mowing lands, some land would not bear it, particularly if wet; but he fed his dry lands very close, in the fall, with cattle and sheep, and experienced no damage from it.

Judge Cheever said he would cut his clover in blossom—not sooner. He would let it take the sun one day, but not enough to have the leaf break off, then put it in small cocks and cure it, until, by a few hours' drying, by turning over and breaking the cocks, the fluids would be so far out of it that it may be housed without hurting. The length of time necessary to cure it will depend upon the state of the weather, and the larger or smaller growth of the crop. Upon this the farmer must exercise his judgment.

He would not cut timothy until it had passed out of the blossom. Professor Davy, in his Agricultural Chemistry, says that 64 parts of clover hay, cut in blossom, produced 10 parts of nutritive matter, and the same taken in seed; timothy 10 parts in blossom and 23 in seed. This, in the timothy, is probably too much; but that the nutritive matter in timothy improved after the fall of the blossom he had no doubt. Red top comes to maturity later, and he did not think there was much difference whether cut in blossom or soon after. He believed timothy cut in blossom would, pound for pound, produce more milk when fed to cows or sheep than it would cut afterwards; but for horses and other stock, he thought it more nutritious to stand a little longer. It certainly improved in weight.

He preferred mowing his hay, as far as he could, when free from dews or water. He let the swaths take the sun a few hours, until the top got a little wilted or seared, before turning. It thus held up the greener parts when turned over and spread, and permitted the air to circulate under it. It also gave the ground between the swaths time to dry, which was important in hastening the curing. In this way, he avoided the necessity of turning the hay after being spread, which was one of the most tedious processes through which the hay had to be passed, and of course the most expensive. He never permitted his hay to take a dew when it had sun enough to wilt it considerably, if he could help it. The dew discolored it, and he had never been able to restore the fine fresh color afterwards. He preferred letting his hay stand over night in the cock. He could then better tell of its fitness to be housed. It is very easy to break up the cocks and give it more sun if necessary, and the slight fermentation or sweating in the cock, which is checked and dried off in carting, is a great preventive against heating in the mow. Hay heated in the mow is sure to be discolored. Some people insist that it is not injured for feeding, especially to cattle. It may be so. I know that flour, corn, or oats, which have been heated until they are musty, are thought not so good. I do not know why hay should be.

On the approach of rain, I always put all the hay that has had any sun of consequence into the cock. If the storm is a long one, it may turn yellow, so that it cannot be restored, but it will retain most of its nutritive matter and its weight; whereas, if left spread out to take the rain, it loses both, and is much worse discolored. I never use salt upon my hay but upon compulsion. When the weather is good, I dry my hay sufficiently to keep, and as soon as I can I house it; but sooner than leave it out to take a storm, even in the cock, I would put it in a little short dried, and apply salt to save it, as I would sooner have it salted than musty.

Dr. Lee thought it the best way to mow grass after the dew was off; spread it, dry it as much as possible, and rake it into winrow. If it was dried enough—and it would frequently be so—he would load it from the winrow, and save the labor of cocking it up.

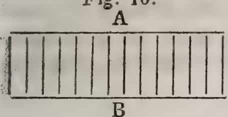
The above table, showing the results of an experiment given in the Journal of Agriculture, for the purpose of proving the best depth for burying the different kinds of grass seed, cannot fail to be interesting and valuable to our farmers. It was performed as follows: Two boxes, each one foot wide, and five feet ten inches long, were filled with soil—No. 1, to within a quarter of an inch of the top; No. 2, to the top on one side, regularly sloping to within three inches of the top on the other side. Both boxes were then divided across by slips of wood a foot long and two inches broad, so as to leave fourteen spaces, one foot long, in each box. Fig. 16 will show these divisions—box No. 2 being filled to the top on the side A, and three inches from the top on the side B. The same weight of seed was sown in each box, the slips of wood were removed, and the boxes filled to the top with soil. The seed in box No. 1 would thus be all buried a quarter of an inch deep; and in No. 2, from no depth to three inches. They were placed in a green-house, for the first ten days, to prevent the risk of heavy rains, which would have crusted the surface. This may have caused the seeds to spring from a greater depth than under other circumstances.

Fig. 16.



The quantities of each sown, (except timothy, which was about double the rest,) were such as would have produced about the same number of plants to an equal surface; but the experiment being performed in summer, (August 1,) the different kinds had variously diminished in vegetative powers. This diminution with clover is such that the experimenter, S. D. Stirling, remarks, that cloverseed "kept over one summer would be dear at half price."

The whole furnishes a striking exhibition of the loss sustained in all cases by harrowing grass seed deeply into the ground. This is especially the case with very small seeds, as timothy and wood grass—none of the latter vegetating an inch beneath the surface, though this remark would more strongly apply to a heavy than to a light soil.

The writer also makes the excellent recommendation to "all who would avoid disappointment, to prove *all* their grass, clover, and turnip seeds before sowing, by sowing a small weight in a pot, and placing it in a warm situation, and counting the plants which come up"—by which they will often find that 30 pounds in some cases will be cheaper than 20 pounds in others.

The scientific names of the plants are given to prevent mistake where different common names are known in different districts, and which have enabled us to add or substitute some common names in place of those which are nearly unknown to our farmers.—*Cultivator.*

SOWING OF GRASS SEEDS.

The fifth monthly meeting of the "Stirling Agricultural Improvement Club" took place on the 14th of April, 1843, when, after some preliminary business, the following paper, on the sowing of grass seeds, was read by Mr. David Drummond, of the Agricultural Museum, Stirling, and 58 Dawson street, Dublin. A lively and interesting discussion took place. The members then resolved:

1st. "That the land should be well pulverized and rolled, immediately prior to sowing the grass seeds; the seeds should then be carefully sown, and covered in as *lightly* as possible, and again rolled."

2d. "That the quantities and varieties specified in the essay are, in the opinion of the club, well adapted to the generality of soils."

On the sowing of grass seeds.

There is perhaps no branch of cultivation where so much of what may be called random practice has existed, or where the execution of the work on correct principles will tell with more effect, than in the sowing of grass seeds. It is a subject on which a great deal might be said; in a comprehensive view, however, the following remarks will, we conceive, embrace the most essential points.

I.—*Preparing the ground to be sown.*

It is almost needless to say that the land should be in good condition, well worked, and free of weeds, which it generally is after green crop or summer fallow; the usual way is to sow the seeds immediately before the last turn of the harrows, when grain has been sown, though sometimes a little additional harrowing is given, by way of *insuring* a better braird. I have known no less than three turns of the common harrow having been given to timothy seed: the consequence was that scarcely a plant ever appeared. Instead of all this I would say, roll well, if the weather admits of it; and even previous to sowing, this operation is to be recommended; for the benefit arising from firming of the surface will of itself more than repay the trouble; besides, by thus making an evenly bed for the seed, the foundation is laid for a more regular covering, and the seeds will come up *flush*, or together—a point not to be overlooked, if we would secure the greatest number of plants.

II.—*The kinds of grasses to be sown, and quantity of seed per acre.*

The kinds must depend on the object in view at the time. If hay, and one or more years' pasture in the alternate husbandry be intended, those kinds which yield the greatest bulk of produce and come soonest to perfection are to be preferred, as rye-grass, timothy, cocksfoot, and the clovers. If permanent pasture, those are to be added which further insure the advantage of an early and close sward, and a succession of fresh herbage throughout the year, as meadow foxtail, several of the fescues, meadow grass, &c. The whole family of the graminiæ being what may be called gregarious in their habits—thriving better in company than alone—a variety of species is the surest way to obtain a maximum of produce. All land has a tendency to re produce those plants which are indigenous to it; so that after a series of years, more or less, according to the care which has been bestowed upon its cultivation, the indigenous plants will ultimately supersede those which have been artificially sown; but if we can at once produce the varieties naturally suited to the soil, especially those preferred by animals, by filling the ground with a proper proportion of their seeds, a point will be gained calculated to enhance the value of our pasture land, without having to wait nature's time.

Although, in Great Britain, we possess about 500 graminiæ, we only culti-

vate about *five*, and in some parts only one species—namely, rye-grass. Linnæus remarks, that, out of about 900 plants, the cow eats 286 ; the goat 458 ; the sheep 417 ; the horse 278 ; the hog 107 ; the cow refuses 184 of them ; the goat 92 ; the sheep 102 ; the horse 207, and the hog 190 ; and he further remarks, that those rejected by some are highly relished by others. Under these circumstances, why should the farmer prefer only white clover and rye-grass for pasture, in enclosed fields, into which the live stock are placed, and compelled to eat these crops alone, when, by a little care and attention, other varieties may be sown, tending to preserve the animals in a more healthy state, and producing a more valuable supply for milking and feeding ?

In proof of the theory that many of the natural grasses are preferred by sheep and cattle to rye-grass and clover, Mr. Stirling, of Glenbervie, Stirlingshire, made an experiment by dividing a field into ridges, and sowing every alternate pair with different kinds of seeds. The following spring, sheep were enclosed in the field, and allowed to roam at large. After having the liberty of all the varieties for months, the rye-grass was found almost wholly untouched, while the timothy and some other sorts were cropped to the root; thus proving, to a demonstration, the error of cultivating rye grass only, especially for sheep pasture. Timothy hay is eaten greedily by horses, being sweeter and more nourishing than rye-grass. The crop is also very abundant, four tons per statute acre having been produced at Glenbervie.

The quantity of seed should be regulated according to the nature of the soil, and the object to be attained. The following selection, suggested by experience, exhibits the varieties and proportions most suited for permanent pasture, per statute acre, sown with a crop on *medium soil:*

Perennial rye-grass - - - - -	18 lbs., or $\frac{3}{4}$ bushel.
Timothy - - - - - -	3 "
(H) Meadow fescue - - - - -	4 "
(L) Hard fescue - - - - -	4 "
(H) Meadow foxtail - - - - -	2 "
(L) Cocksfoot - - - - -	3 "
White clover - - - - -	5 "
Red perennial clover - - - - -	3 "
Milfoil - - - - - -	$\frac{1}{2}$ "

When sown without a crop, add about a fourth.

For *light* soil, take one lb. off those marked (H,) and add to those marked (L.)

For *heavy* soil, the contrary.

Italian rye-grass may occasionally be substituted for part of the perennial rye-grass ; it does well in peaty soils.

For alternate husbandry, viz: one year's hay, and one or two years' pasture, per statute acre—

Perennial ryegrass - - - - -	18 lbs., or $\frac{3}{4}$ bushel.
Timothy - - - - - -	3 "
Red clover - - - - - -	5 "
White clover - - - - -	3 "
Yellow clover - - - - -	1 "

If for one year's hay only, use $1\frac{1}{4}$ bushel annual rye-grass ; add 2 lbs. to the red clover, and deduct 2 lbs. from the white ; and the contrary for two

years' pasture. A Scotch acre requires one fourth part more, and an Irish acre fully a half, or a half and an eighth-part more than a statute acre.

III.—*Sowing*.

The regular distribution of the seed is of great importance; for this purpose there is nothing equal to a machine, which can also be used in windy weather. Sowing a variety in mixture with the hand requires considerable dexterity; and, indeed, the work can scarcely be done in that way correctly. Sowing the light separately from the heavy seeds is considered a good practice. It has been recommended to sow first the large and then the small seeds, giving them proportionate degrees of covering; but as the large will do equally well, with that degree of covering which will not be too deep for the small, this appears unnecessary. Calm weather should always be selected, if possible, for sowing grass seeds; and should the weather be wet at the time of harrowing or rolling, a quantity of seeds may be expected to be wasted, by adhering to the roller and harrows. The period of sowing must be regulated by the seed time of the crops with which they are sown, or, if without a crop, any time from March till September.

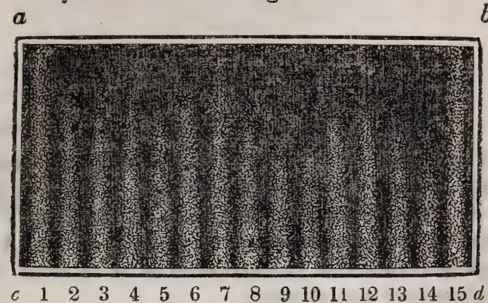
IV.—*Covering*.

In horticulture, it is well known as a general rule, that different seeds require a scale or degree of covering proportionate to their strength and size; yet in agriculture a practice exists till this day much the same, as if the gardener were to sow mignionette in the drills made for peas, or turnip in the dibble hole intended for potatoes; for, by the use of the common sized harrow, a great portion of the grass seeds are as effectually buried as the mignionette and turnip would be. The short-teethed light grass harrow is an improvement, but still too coarse. A harrow formed of *thorn bushes* comes nearer the point, but is inconvenient, and cannot at all times be procured of the right sort. Mr. Smith, of Deanston, having turned his attention to the subject, has supplied the *desideratum* by the invention of his chain-web harrow, which gives the required slight and equal covering in a manner difficult to surpass; for, besides covering the grass seeds effectually, it, from its nature, compresses the surface of the soil to a greater depth than does the roller, and leaves the ground in that state which is so favorable to the growth of grass. This harrow is also valuable for drawing over wheat lands in spring, when the surface has become battered with rains; being constructed on principles which admit of self-adjustment to the surface of the soil, it is, instead of teeth, furnished with numerous little sharp discs, which, revolving, cut or mince, without tearing the plant or turning the clod; for same reasons, it is also well adapted for harrowing top-dressing.

Mr. Stirling, of Glenbervie, who has, in the most practical way, been for several years proving the merits of the different grasses and best method of cultivation, suggested a trial of the most useful of these seeds at various depths, in regular gradation. The following experiment was conducted under our own superintendence in the nursery grounds at Coney Park:

Seeds sown 13th of May, 1842, on an open border of light sandy soil, the covering regulated by a frame standing 3 inches in depth at *a b*, and level with the surface at *c d*—the border 4 feet wide. The white spots

show where the seeds have brairded, and the proportionate thickness of the plants at the different depths, thus proving, to a certainty, the great loss sustained by the ordinary mode of covering the seeds.



No. 1, perennial rye-grass ; 2, timothy ; 3, meadow fescue ; 4, red clover ; 5, white clover ; 6, yellow clover ; 7, rib grass ; 8, meadow foxtail ; 9, hard fescue ; 10, smooth-stalked meadow grass ; 11, cocksfoot ; 12, crested dogstail ; 13, wood-meadow grass ; 14, fiorin ; 15, Italian rye-grass.

The perennial rye-grass alone has grown at 3 inches depth, but after passing the middle or $1\frac{1}{2}$ inch, the plants decrease more than half.

This experiment was repeated in September, on clay soil, when the results were found much the same. The weather was dry ; in wet weather, the probability is, that they would not have vegetated at so great a depth as in the light soil.

Immediately after sowing, weather permitting, the roller should be again used, as nothing seems more clearly established than that grasses thrive best on a firm consolidated surface, as will be seen by the superior growth and appearance of head or end ridges, where, in laboring the field, the horses have trodden by frequent turnings ; hence, where the seeds are sown with a crop of grain, rolling in autumn after the crop is removed, and also the following spring, is of essential benefit ; and if sown without a crop, frequent rollings during the first and second years will be found to improve the pasture, both in growth and thickness.

In regard to the question, whether grass seeds for permanent pasture should be sown with or without a grain crop, I would say, that where it is an object to have a close sward speedily, or where, from the richness of the soil, apprehensions may be entertained of the grain lodging and injuring the young grass, sow without a crop ; but otherwise there does not appear sufficient compensation for the sacrifice, though, in general, it may be advisable to sow the grain thinner than ordinary.

Stirling, *December*, 1843.

APPENDIX No. 8.

HEMP.

LOUISVILLE, *November* 7, 1845.

DEAR SIR: I received your letter of 31st ultimo on yesterday. I cheerfully comply with your request, as far as I can, to furnish you with statistical information in relation to the culture and manufacture of hemp.

I know nothing as to the culture of hemp east of the Alleghany mountains; but I suppose it to be so inconsiderable as to be of no importance in a report of the character you suggest.

I put down the following in round sums as the product of the few western States where it is chiefly grown—viz:

Kentucky in 1844*	22,500	tons.
Missouri in 1844	12,500	
Tennessee in 1844	1 500	
Ohio, Indiana, and Illinois in 1844	500	
	37,000	

Which is thus consumed:

Kentucky, for bagging and bale rope	15,000	tons.
Tennessee, for bagging and bale rope	1,500	
Missouri, for bagging and bale rope	4,500	
Ohio, Illinois, and Indiana, for bagging and bale rope	1,000	
Into bagging and bale rope	22,000	
Consumption of the various towns on the Ohio river, for cordage, lines, twine, &c., say	1,500	
Exported to the eastern cities, say	5,000	
Exported to Europe	100	
Unsold in the hands of farmers	8,400	
Thus exhibiting a surplus product of	37,000	

The experiments made of sending hemp to Europe did not succeed—netting the shippers but about $40 per ton. This is caused, in part, by the heavy expenses consequent upon the shipment and sale; but mainly because it comes into competition with Riga Rein hemp, which can be afforded in England at $140 to $150 per ton of our currency, because England levies only a nominal duty of five shillings per ton on it. This hemp is worth intrinsically $60 to $70 per ton more than Kentucky or Missouri dew-rotted hemp, for cordage, &c., which reduces the market value of the latter there far below what it is worth in the United States.

Very many farmers have made the experiment of water-rotting; but owing to bad success in watering, and worse success in selling, they have

---

* Believed to be for 1845.

nearly abandoned it. None of those who grow hemp largely will water-rot; it is only those who have not slaves, and who grow but a few acres, who will water-rot.

That sent to the eastern cities is used chiefly in the manufacture of cordage, lines, twine, &c.

Kentucky manufactures of bagging, per annum - -	12,000,000 yds.
Tennessee manufactures of bagging, per annum -	1,000,000
Missouri manufactures of bagging, per annum - -	2,000,000
Ohio and Illinois manufacture of bagging, per annum -	1,000,000
New York, New Jersey, and Louisiana manufacture of bagging, per annum - - - - -	500,000
	16,500,000

Kentucky manufactures of bale rope, per annum			-	12,000,000 lbs.
Tennessee	do	do	do - -	1,500,000
Missouri	do	do	do - -	5,000,000
At the east	do	do	do - -	5,000,000
				23,500,000

This amount of bagging and bale rope is sufficient to cover about 2,600,000 bales of cotton.

The price of hemp, bagging, and bale rope has declined almost in the ratio of their increased production: thus, in 1835, with a crop of 7,000 to 8,000 tons in all the western States, it was \$10 to \$12 per cwt., bagging 35 cents per yard, and rope 12 to 13 cents per pound. In 1840, the product had increased 50 per cent., when the prices were—hemp \$9 per cwt., bagging 25 cents per yard, and rope 10 cents per pound. Since then, under the stimulating influence of the tariff of 1842, the products are four or five times the amount that they were in 1835, and the prices now are \$3 per cwt. for hemp, 8 to 9 cents per yard for bagging, and 3 to 4 cents per pound for bale rope. These prices do not remunerate grower or manufacturer; and, were either compelled to pay 6 per cent. interest on the capital employed, it would be ruinous.

You will observe that I have before stated that there is a surplus of hemp unsold in the hands of farmers of 8,400 tons; besides this, there is a vast quantity of unsettled land in the western country, suitable for hemp growing, which is fast filling up with a hemp-growing population. At present we consume more than half of the hemp that is grown, in the manufacture of bagging and bale rope; which cannot be increased, unless by increase of the cotton crop, the very low price of which would indicate that it cannot and will not be increased. The whole amount of the crop of hemp of the western States, that is consumed in the manufacture of cordage, lines, &c., is about 6,000 tons. What is to be done with the present and annually increasing surplus? Europe, we see, will not buy of us at remunerating prices.

If the growers would water-rot, and our naval and commercial marine be supplied wholly with it, there would be no difficulty. But how is this to be effected? But in one way: government must set the example in its use, and should not only establish agencies in the west for its purchase in the raw state, but should establish factories to make the cordage—say one in

this place and one in St. Louis; these two points, by direct water communication, would be easily accessible to all the hemp-growing region. Here all the tow could readily be sold to bagging and rope manufacturers; for such is the improvement in machinery, that tow can now be more cheaply manufactured into bagging than best hemp could be five years ago. A majority of the farmers would water-rot portions of their crop, if they had a market at home for it, where they could be assured of obtaining $120 per ton; which, you are aware, is $60 to $80 per ton less than is paid for Russian hemp. The cordage can be manufactured here as cheap as at the east, and the cost of transportation to *any* port of the United States would not exceed $20 per ton; but the farmers will not water-rot so long as ninety-nine hundreths of them are ignorant of the modus operandi; nor while the market is so distant from them as Boston, &c., and while the inspection is uncertain, and returns more uncertain.

Your letter did not invite the last paragraph; but I hope you will not consider it obtrusive, and also superfluous, inasmuch as your position brings you in contact with every matter or thing for the promotion of the interests of the artisan and agriculturist.

If what I have written should be of any service to you, as a small mite, in making such a report as will develop the resources of this great country, and be the means of enlightening our law-makers and pointing them to some interests which need encouragement, I shall be amply compensated for the few minutes I have expended.

Very respectfully, your obedient servant,

THOS. S. FORMAN.

EDMUND BURKE, Esq.,
Commissioner of Patents, Washington, D. C.

P. S.—It is perhaps proper to say that I have been a grower and manufacturer of hemp for fifteen years.

USEFUL METHOD OF ROTTING FLAX AND HEMP.

[Translated from the Polytechnic Archiv, Berlin, 1841, by E. Goodrich Smith.]

Dr. Scheidtweiler, professor of Botany in Brussels, has introduced the following mode of rotting, which is much recommended: A wooden box, six feet long, broad, and high, and therefore containing two hundred and sixteen cubic feet, has over its bottom a second floor, five to six inches above the lower one; this upper one is perforated with holes; a hole is also made in one side of the box close above the lower bottom, which is stopped up with a bung, in order to let off the water which may be produced in the course of rotting. Upon the upper perforated floor let there be a layer of straw three to four inches thick; on the straw the flax or hemp is to be spread as uniformly and closely as possible, to fill as much as three-fourths of the depth of the box.

When the flax has been spread, then place again a layer of straw of the same thickness as the former, (three to four inches.) Now let the box be filled with river, or, what is better, rain-water, and cover the whole with a top, likewise perforated with holes.

According to the temperature and the degree of dryness of the flax, allow it to soak for from twenty-four to forty-eight hours; then open the bung-hole in the bottom, and draw off the water, and let the flax be trodden down close together with the feet.

When thus trodden down and covered with a layer of straw, the flax, according to the degree of warmth of the atmosphere, will more or less soon become rotted; and, in this method of rotting, it is of the utmost importance so to conduct the rotting that the interior heat shall never rise above from 30° to 36° Reaumur—about 134° to 162° Fahrenheit. On the first day the heat inside the box rises not above the surrounding atmosphere. The day after, it reaches to 20° R., (or 90° Fah.,) and gradually increases up to 70° R., (or nearly 320° Fah.,) on which account the precaution must be taken of pouring in a dozen or more pails of cold water, according to the quantity of flax in the box. If the whole apparatus is placed in a warm place and protected from the cold winds, then cooling it off twice in twenty-four hours is sufficient; but if it is already cool, then once cooling with water is enough, in the same time. In this we must be governed by the thermometer, which is tried in the midst of the layer of flax, and the heat must not be allowed to exceed 36° Reaumur, (or 162° Fahrenheit;) over 40° R., (or about 180° Fahrenheit,) the flax is in danger of being spoilt. On the third day take out some stalks for trial, and see whether the flax has rotted to that usual degree in which the fibre is stripped off.

To aid the process, place four or five inches of wood ashes on the upper layer of straw, on which gradually, and in small quantities, pour water; the ley from the ashes will then fully act on the gummy parts, without attacking the fibre. Finally pour on again some pailsful of water; let it be drawn off; take out the flax from the box; wash and dry it, either in the air or a gentle heat of an oven. The use of ashes is not necessary, but the fibre will be better cleansed, and contain less tow. If, on drawing the stalk through the fingers, it shows itself still of a greenish color and glutinous, the rotting is not complete, and the flax must remain in the box a day longer.

If we employ the ley on the second day, the rotting will be aided. The rotting can be carried on during the whole year, if there be a drying room or an oven. As the process occupies only three or four days, all the flax cultivators can use the same apparatus, and thus avoid the injurious and unhealthy consequences of the usual mode; a single proprietor of such an apparatus could do the rotting for a whole township. By practice, the process may be yet more perfect, and the loss in tow, &c., lessened.

LA FRANCE INDUSTRIELLE.

From the same, page 160.

MACHINE FOR PREPARATION OF FLAX, &c.

According to the transactions of the Industrial Union for the kingdom of Hanover, a Holstein farmer has invented and constructed a machine of wood, by means of which, he states, he can clean flax merely dried in the sun, without any rotting, as it is called, or having undergone any chemical preparation, so perfectly, in twenty-four to twenty-eight hours, that it far

excels the threads of flax which are derived from the usual process. The machine, too, whether of wood or iron, is so cheap that any farmer can purchase one. It also prepares a large quantity rapidly, and can be worked by a child ten years old. The specimens of flax prepared by this machine, submitted to the Union in Hanover, were of extraordinary cleanness, strength, and fineness.

WATER ROTTING HEMP.

The subjoined article we find in the Nashville Agriculturist, from the pen of Gen. G. J. Pillow.

I have water-rotted a crop of forty acres of last year's growth, and have not made a single failure; nor have I had any difficulty in determining the point at which the rotting process should cease; nor have my hands been at all exposed; neither is there the least danger to be apprehended of sickness from this kind of labor. But I believe my success is mainly attributable to the construction of my vat, and my preparation for the business. I will first state the character of these: My vat is built near a small creek, which I straightened by a ditch, and thereby gave it a deep channel. The vat is 90 feet long, 20 feet wide, and 4 feet deep. Its walls are built of hard brick, laid in hydraulic cement mortar, and they rest upon a solid stone, which extends clear over the bottom of the vat. The walls of the vat are thus made water-tight, and proof against the action of the water.

To dispense with the immense weight which would be required to press the hemp down, I drilled holes in the stone bottom, along the whole length of the vat on both sides, and within two feet of the walls, the holes being eight feet apart; into these holes I drove iron bolts, with wedges of the same material inserted in the lower ends, as firmly as I could with a sledge-hammer. The upper ends of these bolts have each a closed hook or ring, into which are hooked iron bolts $4\frac{1}{2}$ feet long, with key-holes in the upper ends.

When my vat is filled with hemp, I place cedar logs across the whole width ofthe vat. The upper bolts pass through the ends of these logs, and, with iron keys, the whole are clamped firmly to the rock bottom.

This being done, by the use of a water gate across the small creek spoken of above, the water is raised in height equal to the top of my vat, and it then passes through wooden pipes, of $4\frac{1}{2}$ inches hole, into the vat, and fills it in about three hours. In drawing the water off from the vat, I raise a small water gate which slides in a casting on the inside of a frame, worked into the wall, and the water thence passes rapidly through a ditch, constructed for the purpose, into the main creek. The vat may in this way be emptied in half an hour.

It will thus be seen that with five minutes' labor my vat may be emptied or filled. Within 20 steps of this vat are built my hemp house, the house for my machinery, and a very large shelter to protect my hemp from exposure to the weather, all under one roof.

By having my hemp always protected from the weather, I can carry on any department of the labor without any interruption from rain or inclement weather. In addition to this consideration, (which is very important,) I save a heavy loss which is always incurred by stacking hemp, and I pro-

tect my hemp from the deleterious effects of the weather upon the color, weight, strength, and oily qualities of the lint. In this last point of view, the shelter is indispensable.

Inasmuch as that, in water rotting hemp, it has to be handled a great deal, it is very important to *cut* instead of *pull* the hemp. It is equally important to the after labor to handle it so as not to *break* the stalks nor *tangle* it; but care should be used to lay it down as straight as possible. If this is not attended to, the subsequent labor is greatly more difficult, and the loss from the broken stalks and tangled hemp is much increased.

After the hemp has become wilted by exposure to the sun for half a day, (and, after such exposure, care should be taken to avoid rain or a second night's dew,) it should be taken up and bound in bundles six or eight inches in diameter, and loosely shocked in the field for 24 or 30 hours, so as to dry the tops and leaves, and prevent the hemp from mouldering under the shelter. It should then be removed and packed away under the shelter. It would be preferable (if there were time sufficient) to top the hemp before sheltering it. The only additional preparation necessary, before placing it in the vat, is to top the hemp, bringing it to a uniform length, and placing around each bundle another bind near the upper end, having previously pressed the first bind towards the lower end of the bundle. I have not found it necessary to introduce a stick into the bundle, to support the hemp in lifting it out of the vat; nor do I believe it will ever be necessary, if the vat is so constructed as to draw off the water previous to removing the hemp.

After taking the hemp out of the vat, for the purpose of drying it, it should be opened, and spread against something which will support it in an erect or inclined position, and keep it off the ground. If suffered to come in contact with the ground, the dirt adheres to it, and will in some degree injure the beauty and whiteness of the lint, and make the process of breaking and cleaning it more difficult and unpleasant.

The length of time required to rot hemp in water depends very much upon the quality of the hemp, and the character of the weather. The large and coarse hemp will rot much quicker than will the small or fine hemp. Care should therefore be taken to bind the small hemp by itself, and not to place the coarse and fine hemp in the vat at the same time.

If the weather is warm, and the same water retained, ordinary hemp will rot in from six to ten days. If the water is frequently drawn off, and pure and fresh water supplied every day or two, it will require two or three days longer; but in the latter case the hemp will be much cleaner, and brighter, and softer, and it will lose less in preparing it for the manufacturer, than if kept all the time in the same water.

After the hemp has been perfectly dried, it should be tied in bundles again, and removed to the shelter, where it will remain free from damage until it suits to apply it to the brake. After taking it from the brake, it should be run through the hatchel, so as to straighten the fibre and extract the tow from it. The hemp which remains is most beautiful, surpassing in brightness, length, strength, and glossy appearance, any hemp I have ever seen. The tow which is thrown off from the brake is less in quantity and superior in quality to the tow from the hand brake. This tow, as also the tow extracted by the hatchel, I straighten by again running it through the brake, (by which process it is cleaned almost perfectly of the sheaves,) and sell to our home manufacturers for making rope and baling. Care should

be used, after hatcheling the hemp, to keep the butt ends of the lint all together, and to keep them all as even as possible. Being thus handled, will contribute greatly to the ease with which it can be handled and separated by the manufacturers, without its becoming tangled; whereas negligently and carelessly putting it up, by mixing the tops and butts of the lint together, will very materially detract from its value in the market. In this latter condition it will not be received at all at the navy yard of the government. Being hatcheled and thus arranged, it should be bound tightly around the butt ends of the lint, in bundles of 8 inches in diameter, and in that condition baled up, without being twisted at all. In baling, the ends of the lint may be doubled over so as to make the bales of proper length. The hemp should all be assorted—that is, the long hemp should be bound and baled by itself, and so of the shorter quality. In order to protect the lint from dirt, and the consequences of roughly handling during transportation to market, its whole outer surface should be covered with ordinary baling of other canvass.

WASHINGTON CITY, *January* 8, 1844.

SIR: The following treatise on the culture of hemp, and water-rotting, is submitted to the farmers of Missouri and the adjoining States:

The land best adapted to the culture of hemp is that which has been timbered with black walnut, buckeye, hackberry, and a reasonable proportion of white oak; or rich bottom lands answer well. The land should be ploughed deep, and well harrowed before seeding. If sod land, it should be ploughed down in the fall, to receive the winter frosts; and when time for seeding, (which is from the 1st of April to the 10th of May,) it should be well ploughed, harrowed, levelled, and smoothed. The seed should be sown broadcast, one bushel and a half to the acre. When the blossoms begin to fall, (which is from the middle of July to the 1st of August,) it should then be cut. Hemp left standing too long injures the staple, and produces a harshness and weakness. It should be cut before it is ripe, which is before the blossoms begin to fall. By attending to this, particularly, you will find the lint heavier, as it will retain its oily substance, (what is termed the essential oil,) which, by being left standing until ripe, the action of the atmosphere, as it ripens, causes to leave it, which produces a lightness and harshness in the lint, and deprives it, in a certain degree, of its elasticity; consequently, when the hemp is applied to the hatchel, the staple breaks into small fibres, which are converted into tow; and when the tar is applied to it, and converted into cordage, it becomes stubborn and brittle in frosty weather, and consequently not so durable. Any chemical process, or any other mode to produce a rapid solution of the gum, extracts the oil, weakens the staple, and produces the former injurious effects.

The instrument for cutting is similar to the point of an ordinary scythe; it is about two feet long from the point, with a socket standing at right angles with the face of the blade, and angling to the edge, to prevent the person, when cutting, from bending too much, as it is necessary for him to stand upright as much as possible to keep the hemp from tangling. The hemp should be cut as close to the ground as possible, and, for watering, it should have the tops cut off as far as the seed ends, and thrown into the shade or kiln-dried. The drying in the shade retains its natural color, and

causes the essential oil to be retained. The kiln-drying has the same effect, but is a more rapid process. The sun produces a harshness when rotted, and the dew discolors it and produces less weight. Pulling hemp is not recommendable; it injures the soil as well as the quality of the hemp—more particularly that of water-rotted. When cutting, all the large hemp should be laid by itself; it should be bound up into bundles, with two bands on them, about the size of six or eight inches through in the butts. When too large, they are awkward to handle, which wastes the hemp. Also, place sticks in the centre of each bundle, about one inch in thickness or more; it prevents the hemp from breaking and tangling when rotted, and will assist to facilitate the workmen in handling it: the same sticks will answer for a whole crop. If your pools are prepared, commence filling them; and be particular in selecting the size of hemp, placing the large in a pool by itself, and the small also in a pool by itself, as the large undergoes a more rapid solution when immersed. The hemp placed in the pools should be carefully packed down with narrow plank laid on the points and butts, and with rock or timber to weigh it down; rock is preferable.

No hemp less than five feet should be water-rotted. Sizes under this may be dew-rotted. It depends upon the temperature of the weather in what length of time it produces maceration. In the month of August, it takes four or five days; September, six to eight; October, ten to twelve; December, three or four weeks. After the fourth or fifth day in August and September, the sixth or eighth day in October and November, and the third week in December, or less time, it should be carefully examined, to ascertain when it has fully come to its solution. You will discover that the stalk has a roughness on the surface previous to its being placed in the pools. When the solution has arrived to its extent, by drawing a few stalks out of the bundles in the centre, promiscuously, and passing your hand along the stalk, you will find the roughness has left it, and that it is smooth to the touch. The hemp is then finished; take it out immediately; spread it on the ground; and when perfectly dry on one side, turn it over for the other—say for two or three times—until you find that the pith has hardened. If it should receive several rains, it does not injure, provided you attend to turning it. The rains wash off the gum which lies on the surface of the lint; and when applied to the break, it produces a clearer staple, cleans easier, and makes less tow.

There is also another mode, when the stalk will break off short, and free itself of the lint; but the former is the most certain. The hemp, as it is dried, should be thrown into shocks or ricks, well secured from the weather penetrating their centres. If the weather penetrates the centre, it will injure the staple by reducing its strength. In breaking the hemp, it should be broke in small hands, about one-third of the ordinary size. In all my experience I find our hemp requires to be properly hatcheled to stand the test the government requires. This is entirely owing to the different mode of handling to Russia hemp; but by breaking in small hands, it relieves itself of sheaves, and produces less tow, and comes nearer to the quality of Russia Riga Rein, which quality of hemp the government uses for the navy. It should not be applied to the break too often, nor the breakers suffered to practise the habit of breaking dew-rotted hemp, by beating it over the break to relieve it of the herds. It should be thrown up loosely into the atmosphere to let the air pass through it. In drawing your hemp, you should draw it from each end, so that the staple will draw clear, and

have an even hand. See particularly that the butts of the staple be even, and that all the drawings be handed to itself, and not placed in the prime hemp, as it is the habit of doing in dew-rotted. All hemp with the drawings secreted in the centre will not pass inspection. The hemp must be perfectly clear of sheaves, and that must be effected not by little breaking and beating across the break, but by plenty of shaking. I have had the strongest evidence, in all my operations, that hemp broke in small hands, say 10 or 12 stalks at a time, will yield less tow in hatcheling by 20 to 30 per cent., if the hemp is properly rotted. Also scutcheling helps the hemp greatly, and causes it to yield less tow, and straightens out the staple.

This process is very indispensable to produce a merchantable article. The instrument for scutcheling is a flat wooden or iron knife, in the form of a paddle. The hemp is placed on a board upright, about four feet long; one half of the length of the hemp is held by the left hand at the top of the board, and the right applies the knife, which, when properly applied, relieves the hemp of the small sheaves which adhere to it, and straightens the staple for the hatchel, which adds greatly to the value of the article, and consequently produces less tow.

If the farmers have a desire to arrive at that stage in their staple to be equal to Russia, it is indispensable for them to adhere to these instructions. There is no more labor attending water rotted hemp, if properly prepared for operation, than dew-rotted. Hemp water-rotted judiciously, and handled properly, will gain from ten to fifteen pounds on the hundred above the dew-rotted, which more than amply pays for the difference of labor or expense in preparation. This has been proven to be the fact by those who have tested it at one of my pools in Kentucky, and also by an experienced farmer in Missouri. Hemp that is darkened by the dews, or colored water, which is produced by the blackness of the soil, will not meet with a favorable demand in the eastern market; it partakes of the character and price of dew-rotted hemp. To avoid this, immediately after your hemp is cut, place it under shelter, or shield it with inferior hemp, that the dews or rains will not affect it; and also let your pools be made of plank, or otherwise place them at the side of the stream, and dam it sufficient in height that, in case the stream should be disturbed by rain or freshet, it does not pass through your pool.

The construction of pools is as follows: Small spring branches dug down two or three feet; a levee thrown up around them, and small flood-gates at each end, made simply out of four pieces of boards a foot wide, and two feet long. A waste gate around them to let the water pass around, and not into the pool; if so, it produces an uneven temperature of the water, and the hemp becomes irregular in its solution. The pools can be made of plank, and the water pumped into them supplied through a small leaden pipe by an ordinary lifting pump. A pool 40 by 60 feet, 2½ feet deep, will receive three to four acres of ordinary hemp. The pool must not be over 3 feet deep; it will produce an irregular solution, owing to the uneven temperature of the water. To water-rot in ponds or large streams is not so commendable, particularly running streams. The hemp becomes irregular in its solution, and loses its lint. The preparation necessary is to have two long saplings; pin them at each end with cross bars, forming a raft, with uprights at each end; their length to be the depth of the water. These form a raft, say 20 or 30 feet long; load your hemp on them, and sink them with rock. For the conveyance of water to and from your pools, I

will call your attention to the leaden pipes manufactured in this city by Mr. W. W. Thompson. These pipes will be a great acquisition for this purpose, as also for watering stock and avoiding waste of water. They can be made any length, and at a much cheaper rate than an ordinary spout. To those farmers who are not in possession of springs, they can fix a small lifting pump in any part of their farm, and supply their vats with water.

As regards the process, there need not be the slightest apprehension as to deleterious effects to health. As a demonstration of this fact, in my operations for the government, I had about 200 men at various pools in the hemp-growing region in Kentucky, from 1840 to 1841, in a circuit of 100 miles, and there was not one instance of sickness, although many of the men exposed themselves to the water when it was not necessary. I also advise gentlemen not to attempt to deliver more than one ton of hemp to each laborer they have, and not to exceed from 5 to 10 tons the season; beyond this, it will produce difficulties.

I will also observe the necessity of watching your hemp closely when near the time of its full solution. If you permit it to have too much rot, it will injure the hemp seriously in strength and in weight; and to avoid this to those that are not particularly acquainted with its proper solution, they may take it out before it is carried too far, and spread it down upon the field for the dews and rains to finish; but at the time, be particular to attend to turning it, that it may receive an equal proportion of dews and rains throughout. Hemp rotted in the spring is not of as good quality as that rotted in the fall—say the months of October, November, and December. The spring rot produces a lightness of color, and the staple is weakened and loses much in weight. This is produced by the state of the atmosphere, and the sudden and extreme changes of it; and also the hemp lying in the stack after being a long time cut, undergoes what is termed a sweat, which changes the state of the staple. In all the hemp-growing regions of Russia, the crops amount yearly to 90,000 tons. The best hemp produced is in the government of Cheiringoff. The hemp is mostly of short staple, and of the very best quality—the produce is about 15,000 tons yearly; and in part of the government of Orel short staple is also produced, and carried to the port of Riga; but the greater part of the hemp produced in this government is long staple, of which the produce is about 14,000 tons. The hemp of Koursk is mostly long staple, and the produce is about 13,000 tons. The hemp of the government of Tooler is also long staple, and produces about 8,000 tons. In the governments of Tamboff and Riazan, the produce is about 14,000 tons, but not of good quality, being more after the color of flax, and its staple is weak; it is chiefly produced for the Archangel market, and a portion of it reaches St. Petersburgh. The hemp grown in the government of Smolenski is of short staple, partakes of the character of that produced in the governments of Tamboff and Riazan, and which is mostly manufactured into sail cloth fabrics; the produce is about 8,000 tons. The government of Calonga produces about 7,000 tons, mostly short staple. The Russian mode practised in preparing their hemp differs only with their instruction in relation to the care and pains taken in preparation. A portion of the country also adopts a chemical process to produce a rapid solution of the gum, which is injurious to the staple. As this country is subject to frequent hail storms, the crops oftentimes fall short of this.

In laying this information before you, my object is to convey to you the

quantity and the various qualities of hemp produced in the hemp-growing regions of Russia. You will also notice that we have a decided advantage over the Russian article in comparing the small quantity of long staple to ours, as all our hemp generally is of long staple; therefore, by assiduous attention to the culture and preparing of it, our staple must and will have the ascendancy in the European market. In a reasonable time, Missouri can supply the whole world with hemp; as well must Illinois and Iowa arrive to be extensive hemp-growing States, and of a superior quality. And let the agricultural interest of these States buckle on their energies and industry, and consummate it, to the advancement of their own prosperity and the country in general.

I have had the assurance recently given me from a gentleman direct from London, of the highest standing in mercantile transactions, that the moment we are prepared, he will effect a contract to supply the British government with our hemp for the navy, which consumes equal to our navy, and our commercial enterprise—about 12,000 tons yearly. Also the consumption of the port of London is 20,000 tons yearly, embracing the requirements of the navy. I have also had the assurance, from a gentleman of high standing in commercial transactions in France, that, from the character of our hemp, the moment the country is prepared, he will effect the supplying of the French navy with our staple. These countries are desirous to encourage us, that they may have two markets to flee to in case of any warlike disturbance.

I have labored hard, with great sacrifices of interest, for these four years, with the pleasing and proud anticipation to see the country independent of this foreign staple, and that we may become heavy exporters; and the day is not far distant when these anticipations will be fully realized.

And to facilitate this most important object, I have, by the solicitations of a number of gentlemen, delegates from the west, and others in power at this city, consented to embark upon this arduous and hazardous undertaking, with the view of supplying the navy with American water-rotted hemp from the west for a term of years. I do assure you, gentlemen, that no pecuniary inducement could have influenced me to embark upon this work of enterprise again. But something must be done to keep alive and finish this great work, which has been commenced and is in progress, to its ultimate accomplishment. I have lost a large fortune in establishing the practicability of it, and have undergone great afflictions; in consequence of which, I have felt reluctance to subject myself to a second trial of the various circumstances which befel me in effecting that important object. But, with a desire to promote *the agricultural interest of the west, and to see my country speedily independent of this foreign staple*, and with the confidence that I have in you, that you will support me in this act of enterprise, I now come forward once more, with all my resources and energy, to give this subject additional impetus, that will convince the world that this republic can stand free and independent, and can supply the commercial world. To accomplish this great work, I lean upon you, *the farmers of the west*, to rally to my aid, and give me your prompt and energetic co-operation. *And to you, enterprising eastern men, I invite you west*, to establish your ingenuity and enterprise in machinery for the manufacture of fabrics. Your interest, farmers, your prosperity, and your duty as patriots, and as an example to the rising generation, demand your prompt and undeviating attention to this important subject. * * * The question no

doubt will arise in your mind, how is all this to be accomplished? I will answer briefly. Let every farmer take four acres of his best land, sow it down in hemp, and follow my instructions laid before you to the letter. If you have not water convenient, build plank vats 25 feet by 14 and 2½ deep; pump the water into them when the hemp is laid in. They require but a small quantity of water; two men can pump sufficient water in a day, and the same water, with a small portion of additional fresh added to it if necessary, will answer for two or three rottings. This size vat will answer for a crop of 25 or 30 acres, which is more than one farmer should undertake the first year. Four acres of good ordinary hemp, judiciously rotted, properly cleaned, scutcheled, hatcheled, and well prepared, will yield to the farmer a clear gain of all expense of $150 or more. What can be a greater encouragement in an agricultural pursuit than this? In addition to this, a steady market, with the assurances that if you produce a prime article, the highest cash price is ready for you according to its quality, delivered at the various points of agencies. Those persons wishing to see me can address me at St. Louis, post paid. I will either wait upon them personally, or answer them from any State that feels a desire to embark in this enterprise. I am candid to inform those that have never water-rotted, that there is more labor attending this operation than they imagine. But do not be discouraged; experience and time will overcome it in a very great degree; with perseverrance and industrious attention, not relying upon the care and attention of your negroes and laborers, but by your own close attention, you will see great advantages to be gained in the prosecution of this business. I can with confidence and in truth say, that with practical experience and perseveance, they will be found worth more than all the theory and negroes in existence, in the saving of labor, expense, and the quality of the article produced. They will overcome difficulties and objections which first present themselves to you in its incipiency, which finally become obstacles of *minor consideration.* Therefore be not deterred when they are met; but persevere and acquaint yourself of the most practical and economical manner to exercise in the water-rotting process. My plans are laid before you; practise them, and you will improve on them. Practice makes perfect, and opens to you advantages that can be applied to great improvements and economy.

Hemp for the navy must not be less than four and a half feet in length, a clear staple, of proper and natural strength, preserved by judicious treatment, and of a bright color; dark hemp will not be received for that purpose. It will be received and appropriated for commercial enterprise, at a reduced price.

It is the desire that the farmer will practise the mode of scutcheling to relieve the hemp of the herds, in the place of applying it so often to the break. It straightens out the staple, and produces much less tow when applied to the hatchel. Also that they should become familiar with hatcheling of hemp generally. It adds greatly to the character of the hemp, east and abroad. And to those that wish to purchase hatchels, they can be obtained at St. Louis for five to six dollars; or any ordinary blacksmiths can make them, provided they understand setting the teeth, (it greatly depends upon this.) If the teeth are not properly set, it will split and derange the staple and produce much tow. All hemp delivered unhatcheled will be received and paid for according to quality. It has been the practice to

use great deception in the preparation of this article, by secreting the drawings and sheaves in the centre of the heads. But it will be useless to attempt this, as they are sure of being detected.

There are four classes of Russia hemp—Riga Rein, clean St. Petersburgh, half clean, and out-shot. And it is the intention to classify our hemp to the same, and the price paid will range up to eight dollars per one hundred and twelve pounds, delivered at St. Louis, for that quality of hemp that will stand the test that the government requires. And that can be effected and produced by judicious rotting, scutcheling, hatcheling, and of a proper length. That the hemp may be inspected and selected without prejudice to either party, there will be honest competent men from the east, who are fully acquainted with the qualities of Russia hemp, and more particularly that article the government requires, whose hands it is to pass through before it will be paid for.

I conclude this subject with a conviction that this appeal will not be in vain, and that in three years the foreign article will be entirely excluded from our ports, and heavy exports made to Europe.

And I will impress upon your minds the importance of adhering to these instructions; and when your hemp is ready for market, by calling upon Messrs. W. W. Thompson & Co., of St. Louis, or the subscriber, you can obtain any information in regard to the final disposition.

DAVID MYERLE.

St. Louis, *Missouri.*

HEMP.

One of the editors of the Louisville Journal, now in Boston, writes as follows in relation to the increased consumption of American hemp:

"I find that the consumption of hemp at Boston and New York has increased marvellously since last summer. An extensive establishment at Plymouth has manufactured twenty five gangs of rigging this year of American hemp, and but six of Russia, whereas last year it manufactured not a single gang out of American hemp. The American dew-rotted hemp is now used almost universally for standing rigging, and it is getting fast into use for running rigging. Sales are now making here, at six months, of a good article of dew-rotted at $100, the range being from $90 to $100. Some lots have been shipped from New Orleans to Boston this summer at less than $3 a ton; but, as freights are now $11 to Louisville, the whole freight amounts at present to $14 a ton. Nothing but this new demand for hemp for naval purposes could have prevented it from sinking to nothing. The foreign demand is also taking off a good deal at present prices, at least for some time.

"Cotton duck has almost entirely superseded Russia for sails. A merchant who formerly imported and sold a large quantity of Russia duck informs me that he has had a lot of it on hand for three years. It is no longer imported, and the demand has nearly entirely ceased. Cotton duck does not handle as well as hempen, but it is more durable and cheaper, and holds the wind as well. It will enjoy the preference until the Kentucky

hemp duck takes the field; then, of course, it will retire, except for small craft in the coasting trade."

From the Prairie Farmer.

HEMP PURCHASES AT THE WEST.

The Louisville and St. Louis papers have complained much, that the instructions of the Navy Department to hemp agents have rendered nugatory the intentions of the law of Congress, providing for the inspection and purchase of hemp, passed September 11, 1841. These instructions have been such as to prohibit entirely the purchase of western and southern hemp, the growing of which, it is claimed, the law was passed to encourage. These instructions are now rescinded, so that the article may be purchased in Louisville and St. Louis instead of Boston. American hemp is declared to be fully equal to the best of foreign, and we are glad to know that obstructions to its production are removed.

TO HEMP GROWERS.

The following letter is from a gentleman who is exceedingly well versed in all matters pertaining both to the culture and manufacture of hemp, and contains some important suggestions, which we think hemp-growers should give heed to. All who have paid any attention to the prices current of New Orleans, New York, and Boston, must have observed that hemp of *light* color has been generally sought for, while that of a *dark* color has been generally neglected:

Franklin House, Louisville, *August* 1, 1845.

To the Editors of the Louisville Journal and Dollar Farmer:

Gentlemen: Having had some experience in the manufacture of hemp in Kentucky, and knowing something of the fluctuations in price and varieties of quality for different purposes and different markets, I venture to make a suggestion to the farmers in the hemp-growing region of Kentucky.

It is known generally that there will be at the end of the present season a very large amount of bagging and rope left over, though the cotton crop this year is expected to be very large. The result will be that sales will be made at ruinous rates, if sales have not been, and are not now, making at those rates. Now, when the new crop of hemp comes in, what can be the expectation of the farmer? We see at once the manufacturers cannot give a price that will pay for raising it. Shall we have another market for it in the North? But that market cannot be beneficial to us, unless the hemp be of a quality and *color* that will suit it. And, in order to have such, the hemp must be managed in the following manner: As soon as the hemp is cured enough after cutting to stack, it should be stacked, if possible, without rain. There let it remain until frost in November, when it may be spread out. This secures the light color which is sought after for the eastern or northern markets. And should one-half the present crop in Kentucky be of that light bright color when ready for market, I

have no hesitation in saying it would meet a demand and price that would greatly benefit the grower. I have no expectation that the price would be much beyond the price the lead-colored hemp would bring from the manufacturer here; but a division of the crop in this way, half at home and half abroad, will insure a demand for the whole crop, be it ever so great.

TO GIVE WATER-ROTTED HEMP A LIGHT COLOR.

The following note, from an eminent citizen fully conversant with the culture and manufacture of hemp, sustains completely the views of a letter which we gave a few weeks ago, and deserves the careful attention of all hemp-growers:

To the Editors of the Louisville Journal:

GENTLEMEN: In 1822 and 1823, Nathaniel Hart, of Woodford county, Kentucky, stacked his hemp of bright color, and kept it in stack sixteen or eighteen months. He spread it out to water in November, and took it up at the usual time in the winter or spring. The result was a beautiful white hemp, having in all respects the appearance of water-rotted hemp, and I believe every way equal to it. Mr. Hart, in 1824, published in the Kentucky Farmer the result of these experiments, and, as an inducement to produce such hemp, offered to purchase it at a high price; yet very little hemp has been so prepared in Kentucky. I saw yesterday, landing from the Blue Wing, four or five tons of such hemp, grown by a Mr. Cowan, of Boyle county, sold by Mr. Bowman on the wharf for one hundred and two dollars per ton. The large crop of hemp now in stack makes the present season a very favorable one for beginning to produce this kind of hemp. I hope some experiments of this kind will be made in Jefferson county of the hemp now in stack.

E. G. M'GINNIS.

LOUISVILLE, *September* 25, 1845.

From the St. Louis New Era.

HEMP.

The following fact was submitted to me (to assign the cause) by the Navy Department:

"The American water-rotted hemp, when made into cordage without the application of tar, proved to be greater in strength than Russian; and the application of tar proved to depreciate its strength to that of Russian."

It is well known that our hemp, properly prepared, is superior in every respect to Russian; and as this subject is one of great interest to the West, as also of great national importance, I feel a deep interest to cherish that fostering care the government is now extending to this branch of agriculture, and will give you my views in regard to obviating this evil; for, if not attended to, it will produce such a prejudice against the use of American hemp for naval purposes, that in time its use will be abandoned.

The Russian method is to select their male hemp from the female, at the

time the pollen begins to fall from the male, and they also harvest the female before it fully matures. By adhering strictly to this method, the hemp retains the *essential oil.* They also kiln-dry it immediately after it is pulled; the object of doing this is to harden the lint and fix the oil, so that, in the process of rotting, the oil will not evaporate; it is essential that the same method be followed by the Americans.

The hemp should be pulled before the stalk or leaves begin to change their color; when that takes place, it is a sure indication of the oil passing into the seed to complete its maturity; consequently, it leaves the lint, when rotted, harsh, and, with the application of tar, depreciates its strength. Not so with the Russian hemp; the essential oil, being retained, acts as a desideratum for the application of tar, and overcomes the evil which is effected by the heated tar and the spirits which remain in it.

The American farmer, to obviate in a partial manner the evil mentioned, should adopt the method of pulling the hemp, as before described, and immediately place it under cover, to avoid the action of the sun and weather, and remain so for a sufficient time for the lint to harden, which will in a certain degree produce the same effect as the Russian process of kiln-drying. By this means the hemp will retain that most important antidote—the essential oil—from the influence of the tar in its heated application.

DAVID MYERLE.

WASHINGTON, *January* 6, 1845.

From the Louisville Courier, May 17.

AMERICAN HEMP.

In the Courier of yesterday morning we stated that we had seen at the store of Messrs. James Anderson & Co.—the office of the Kentucky hemp agency, under the direction of Mr. Lewis Saunders—a number of specimens of American and Russian hemp, and cordage manufactured from them; and also a machine for testing the strength of the cordage. Yesterday experiments were made upon this machine, the interesting results of which we give below, from Mr. Saunders, the agent. It will be seen from the record that the American hemp not only does not suffer by a comparison with the Russian hemp, but that, in the tests of the larger cordage, it sustained a much greater weight than the Russian hemp. These facts are of deep interest to western hemp culturists, and to the entire country. They show conclusively that as good an article (if not better) of water-rotted hemp can be furnished by the farmers of the valley of the Mississippi as can be obtained from Russia, from whence our government heretofore have obtained all their naval supplies of hemp.

We understand that the mode of curing hemp by the Messrs. Anderson is peculiar. It is neither steamed nor water-rotted, but broken from the stack. The samples of their hemp which we saw, cured by their process, were very superior in appearance to the Russian water-rotted, and we believe much stronger.

HEMP AGENCY FOR KENTUCKY,
Louisville, May 16, 1845.

Commodore Morris, head of the Bureau of Construction and Equipment, caused to be sent to the agency a very perfect apparatus for the purpose of testing the quality of hemp; also a box containing Riga Rein hemp, and a box containing American water-rotted hemp, as samples for examination and comparison. The apparatus and samples of hemp were sent from the Boston navy yard, and arrived here in October last. The object of the department is to give information to the growers and dealers of hemp. By these samples and tests, bidders for the supply of the navy can, with more certainty, submit their proposals.

I caused four parcels of hemp to be accurately weighed, of twenty-five pounds each, and delivered to Mr. Till, (a ropemaker of this place, who learned his trade in Boston,) with direction to make up each parcel separate into $1\frac{3}{4}$ inch rope, and into yarns.

No. 1. Twenty-five pounds American water-rotted hemp, sent from the navy-yard, Boston.

No. 2. Twenty-five pounds Riga Rein hemp, sent from the navy-yard, Boston.

No. 3. Twenty-five pounds cured and prepared by Mr. James Anderson of this place, intended for naval purposes.

No. 4. Twenty-five pounds of a good lot of Kentucky dew-rotted hemp.

The waste and tow returned by Mr. Till from No. 1, was eleven pounds; from No. 2, six and a half pounds; from No. 3, six pounds; from No. 4, ten pounds.

A piece of bolt rope, intended for $1\frac{3}{4}$ inch, made of yarns running 26, was put to the test.

No. 1 broke or parted	at 2,705	pounds.
Same of No. 2 broke or parted	at 2,555	do
Same of No. 3 broke or parted	at 2,940	do
of No. 4 (of $1\frac{6}{10}$ inch)	at 2,415	do

Three-thread spun yarn of No. 1, broke at 400 pounds; of No. 2, at 365 pounds; of No. 3, (hard twisted,) at 362 pounds; of No. 4, at 450 pounds.

Marline two-thread—No. 1 broke at 132 pounds; No. 2 broke at 135 pounds; No. 3 (hard twisted) at 112 pounds; No 4 at 155 pounds.

One-thread, yarns running twenty-six—No. 1 broke at 222 pounds; No. 2 (one-thread spun yarn running twenty six) broke at 108 pounds; No. 3 (same) at 140 pounds; No. 4 (same) at 190 pounds.

Further trials and tests may give different results. They will be made and published.

LEWIS SAUNDERS, *Hemp Agent.*

—

From the Union.

PREPARATION OF HEMP.

We have recently published several articles on the making of hemp. We are happy to have the opportunity of laying the following letter before our readers, just received at the Navy Department from its agent in Kentucky, appointed by the present secretary:

HEMP AGENCY OF KENTUCKY,
Louisville, June 6, 1845.

SIR: The day after the date of my last letter, (16th ult.,) I sat out on an excursion to the centre of the hemp district of Kentucky, through the counties of Franklin, Woodford, Fayette, and Bourbon, placing, for examination and comparison, samples of the hemp sent out from the Boston navy yard, at Frankfort, Versailles, Lexington, Paris, and Georgetown. I had intercourse with many of the principal hemp growers, particularly those that were inclined to water-rot their hemp. I was much gratified in finding a strong disposition on their part to water-rot the crop now growing, to which they are impelled by the present very low price of dew-rotted hemp.

Some knowledge has been acquired by the experiment made in the last few years in water-rotting. It has been ascertained that it will not do to water-rot in warm weather—that it must be done in cold weather.

I confidently believe that the government can be supplied with water-rotted hemp hereafter to the amount of its wants.

Messrs. James Anderson & Co., of this city, have been a long time engaged in making experiments in preparing hemp for manufacturing purposes. Mr. James Anderson speaks now with confidence of having succeeded in curing hemp by heat, to supersede all other methods of rotting or curing hemp. His plan is to break the hemp from the stock by a number of rollers; he then passes it through a fermentation caused by heat, leaving it in a condition to prevent any second or succeeding fermentation.

A bale of hemp thus prepared has been sent to Boston, for the purpose of examination, comparison, and testing. The naval officer, Mr. Parmenter, was requested to take charge of this bale, and attend to the experimental trials.

By this day's mail, I have sent to your address two samples of hemp—one nearly or quite the same as sent before; the other *washed* from the same, marked "refined."

The *refined* is brought to its beautiful silky appearance by washing through several washings of alkalies, and then hatcheled.

There is a strong disposition on the part of some capitalists of this city to engage in the manufacturing of sail cloth of every description. I am requested by them to solicit you to cause to be sent to this agency samples of at least one yard in length of each sort of sail cloth used in the navy of the United States, with a description of the weight and length of each bolt, and the separate value of each. If it is agreeable to you to have this suggestion carried out, you will oblige many of the citizens of this place.

Very respectfully, your obedient servant,

LEWIS SAUNDERS.

HEMP AGENCY FOR KENTUCKY,
Louisville, June 9, 1845.

SIR: In a former letter you were informed that I had got possession of the hemp apparatus for testing the strength of hemp. I secured an eligible position for using it, and a convenient office adjoining, for the use of the agency, for the sum of one hundred dollars per annum, to be paid quarterly.

Persons interested in hemp were anxious to witness the operation of the

machine. I had four parcels of hemp spun into bolt rope—No. 1, American water-rotted hemp; No. 2, Riga Rein hemp, (these two were taken from the boxes sent from Boston;) No. 3, Rhodian hemp, (this is a new article, broke and cleaned without being rotted, either by water or dew. After being thoroughly cleaned, it is put into a close, air-tight room, and then heated by steam until it is sufficiently cured. James Anderson, who claims this discovery, is of opinion that it will answer every purpose that water-rotted hemp will;) and No. 4, common dew-rotted hemp. The rope was not of a uniform size; from which fact, I concluded to make a second test trial, and send you the statement. The editors of the city papers were present, and a number of intelligent gentlemen. The enclosed printed paper is the account of this trial.

At Lexington, I had an interview with Mr. Hamilton, my predecessor. He said he had closed his accounts with the department; that he had no money belonging to the government; that he had kept no book of his transactions as agent. He handed to me some letters and copies of instructions that he had received, and gave me the following list of articles belonging to the United States government, purchased for the use of the hemp agency at Lexington, viz:

One hemp press, Warner's patent, cost $150.

One hatchel.

One desk.

A box of samples of hemp, &c.

The hatchel and box of sample hemp I have directed to be sent to Louisville, and ordered a sale of the desk.

The press is the one most approved by shippers of hemp. It can be sold for nearly cost, or retained for use, should it be thought, hereafter, advisable to purchase hemp in Kentucky.

I have visited the hemp district of most importance in Kentucky—the counties of Franklin, Woodford, Scott, Fayette, and Bourbon; had a free conversation with many growers of hemp, gentlemen of intelligence and liberal views. I am of opinion that contracts could be made for the growing crop, to be water-rotted, from three to five hundred tons, to be delivered at Louisville, of a quality equal to any purchased by the government, at one hundred and fifty dollars per ton.

The counties of Mason and Fleming, in this State, produce large quantities of hemp. The shipping point for these is Maysville. I think of visiting them next month.

Very respectfully, your obedient servant,

LEWIS SAUNDERS.

Commodore C. Morris,
Chief of Bureau of Construction, &c.

Second trial of hemp.

Mr. Saunders, the government hemp agent, made a second trial of the comparative strength of different kinds of hemp, with a result again favorable to the American article. We are glad to learn that similar experiments are to be reported, and that no efforts are to be wanting to settle fully and definitely the comparative merits of the American and foreign articles.

Mr. Saunders has applied the term "Rhodian" to the hemp prepared by Mr. James Anderson by heat, without rotting, called by Mr. Hawes, in his certificate, "Humbuggery," from the name of the place where it is prepared:

KENTUCKY HEMP AGENCY,
Louisville, June 9, 1845.

A second testing, proving the strength of three sorts of hemp, (by the government apparatus,) was made to-day, in the presence of a number of highly intelligent gentlemen.

To Mr. Hawes, a ropemaker of this place, were delivered twenty-five pounds No. 1 American water-rotted hemp, twenty-five pounds No. 2 Riga Rein, (these two parcels are fair selections out of the two boxes of hemp sent to this agency from the navy-yard at Boston, for comparison with Kentucky production,) and twenty-five pounds No. 3 Rhodian hemp. The latter was cured by heat; the method of doing it will hereafter be communicated to the department by Mr. James Anderson, of this city.

Mr. Hawes was requested to make bolt-rope of each parcel of hemp, as near $1\frac{3}{4}$ inch in circumference as he could, to spin the yarns uniformly alike, and to make and lay the rope the same way.

Ten feet in length of each number was cut off and accurately weighed.

No. 1 American water-rotted, ten feet weighed fourteen and three quarters ounces, measured in circumference one and seven-tenths inch, parted at 2,940 pounds.

No. 2 Russia, ten feet weighed fourteen and three-fourths ounces, measured in circumference one and eight-tenths inch, parted at 2,218 pounds.

No. 3 Rhodian, (Anderson's,) ten feet weighed thirteen and one-fourth ounces, measured in circumference one and six-tenths inch, parted at 2,440 pounds.

LEWIS SAUNDERS, *Hemp Agent.*

There will be required many trials before we can designate a standard, but a standard must be established in order to compete, effectively, with the foreign article. In the language of Commodore Morris, we ought to be exporters instead of importers of hemp.

The following is the certificate of Mr. Hawes, who manufactured the rope on which the above experiments were made:

LOUISVILLE, *June* 9, 1845.

In the three lots of hemp presented to me, I found the water-rotted produced more tow than either of the three, and the "Humbuggery" [Rhodian] less, in the same mode of hatcheling.

Respectfully yours,

E. W. HAWES.

Mr. L. SAUNDERS,
United States agent.

In order to make the comparison in the preceding experiments fair, it is necessary to reduce these results to what they would have been with ropes of the same size. We may assume the compactness of the twist and the weight of the fibre to be nearly the same; as the difference in the circumference of the ropes accounts very nearly for the difference in their weights. We shall suppose, then, that each rope had been 1 8–10 inch in circumference. The strength, by a well known principle, is directly proportional to the area of a transverse section; and these areas are as the squares of the circumferences. Take the case of the Rhodian hemp. If 1 6 10×1 6-10 gives 2,440, what will 1 8-10×1 8-10 give? The result is 3,108.

Reducing the result of No. 1, the same way, gives 3,296. So that the experiment may be stated as follows:

No. 1 American water-rotted	3,296
No. 2 Riga Rein	2,218
No. 3 Rhodian	3,108

The difference between the first and third is not more than might be expected in different specimens of the same kind of hemp; whilst the difference between them and the second or Russian hemp is very considerable, and much to the advantage of the former. These experiments will be continued; and we shall have more to say on their importance hereafter.

INSPECTION OF HEMP.

NAVY DEPARTMENT, *July* 18, 1845.

SIR: In the instructions which you may hereafter have occasion to give to the agents for testing, inspecting, and purchasing American water-rotted hemp for the use of the navy, you will authorize the inspection and test that may be made at the several agencies in the hemp-growing regions to be final and conclusive, instead of requiring them to be repeated at Boston.

Whenever it shall become necessary to procure further supplies of hemp, you will direct that contracts be made for its delivery at either of the agencies established; the department to be at the risk and expense of conveying it thence to the Charlestown yard, or wherever else it may be wanted.

I fully appreciate the considerations which have heretofore induced you to require the final inspection to be made at the place of manufacture, and have not, without hesitation, adopted a different conclusion. But, from a careful perusal of the resolutions of Congress on the subject, and the opinions of some of the legislators who assisted in passing them, I cannot resist the conviction that they were designed to encourage the culture of this important staple, by opening to its producers a valuable market in their own region. To require them to sell at an inspection twelve hundred miles distant from their homes, must operate, in a great measure, to deprive them of this market, and have a tendency, therefore, to defeat the expressed intentions of Congress in their behalf.

Entertaining this opinion, and feeling a deep interest in whatever concerns the agriculture of the country, I am induced to hazard the slight inconvenience and expense which may temporarily result to the government from the proposed change, for the sake of the permanent benefit which it may confer upon it in the increased culture, improved quality, and reduced prices of American hemp. While our agents at the west are competent and

faithful in the discharge of their duties, the department may reasonably rely upon them, or upon such special agents as it may appoint, for a safe and rigid inspection of the supplies which may be offered for their approval; and the risk of transporting the quantity thus approved to the place where it is required for manufacture, Congress seems to have devolved, by its recent action, upon the government.

One of the principal reasons which have induced your previous action on this subject appears to be that provision of Congress which requires all supplies for the navy to be furnished, after public advertisement, by the lowest bidder. You will meet the requirements of this law, and the purposes of the Congressional resolves, to which I have referred, by advertising, in the first instance, exclusively for American hemp; and you will allow foreign hemp to come into competition with our own only when the latter cannot be obtained on the conditions prescribed by law.

Acknowledging the interest which you have uniformly manifested in this important subject, and assuring you of the diffidence with which I direct this change in your accustomed action,

I am, very respectfully, yours,

GEORGE BANCROFT.

Commodore C. Morris,

Chief of Bureau of Construction, &c.

HEMP.

We find the following correspondence in the Louisville Democrat, which we give below, with the remark that some of the views of Mr. Barlow should be received, in our opinion, with considerable allowance. We cannot say but that boiling hemp in the stalk may improve it for some purposes; but if, by boiling, "the glutinous matter is fully extracted from the lint," which is very questionable, the hemp would not answer for naval purposes. We believe that nothing is now more fully established, than that the glutinous matter should be retained in hemp for tarred cordage—not that it may take more tar, but less.

Grass Hills, *August* 9, 1845.

It is very gratifying to see so much interest elicited in various parts of the country in relation to hemp. The importance of this great crop, in many parts of the State, is now of the first consideration. Without having yet supplied *any* for the navy of the United States, and but little for commerce, the crop of Kentucky has averaged not less than twenty thousand tons for the last five years.

The passage of the joint resolution by Congress, in 1841, giving the preference to American water-rotted hemp over the foreign article, has turned the attention, *the thought, of many inquiring, ingenious minds* to that subject. The enclosed letter from Mr. Barlow will no doubt be read with much interest. This is the commencement of an *era* in the manufacture of hemp, so ardently and firmly believed in by my friend John George Baxter, (now dead,) more than twenty years ago. Mr. B.'s ideas astounded the incredulous at that period. He asserted that hemp would bleach whiter than either flax or cotton, and make the finest fabric, from lace and cambric down to

good shirting, and far cheaper than either. I will, however, send you Mr. Baxter's paper at another time.

LEWIS SAUNDERS.

WASHINGTON CITY, *July* 25, 1845.

DEAR SIR: I perceive, by your publications, that you are making experiments in testing the quality of the many different kinds of hemp. Having been myself, for the last three years, fully devoted to the subject of water-rotting hemp, and believing that you are desirous to obtain any useful information on the subject, I would beg leave to lay before you the result of my own experiments in the water-rotting process. It is not my present purpose to impose on your attention a history of all that I have done or attempted to do, but will only suggest to you what was finally effected by a regular train of experiments. In the usual mode of water-rotting hemp, much of the good or ill success depends on the temperature of the water and stage of the weather. Under the many different circumstances, a similar fermentation is brought on sooner or later; and after the hemp becomes macerated, the most difficult part of the process is to stop the fermentation or putrefaction at the right point: the hemp often continues to rot even after it is cleaned out and converted to use—ever subject to what is called a dry rot. In order to overcome that difficulty, I put the hemp into strong tight vats, filled with water sufficiently warm to produce an effectual and equal maceration of all the parts of the lint in the same time. Then, by the use of steam-pipes I raised the temperature of the water up to a strong boiling point. The boiling is to be kept up for three or four hours, which will at once fully arrest or dispel all the putrefaction that was connected with the hemp—*cooked, to keep it from spoiling;* in the mean time the glutinous matter will be fully extracted from the lint. The water is then drawn off, and the hemp is taken out of the vat in a safe and sound condition. It may be set out in the weather for a whole year, without sustaining any material injury. It is also free from any short hurds when broke or cleaned, and much stronger than any other hemp that I have been able to compare it with. The lint is strong from end to end, soft, and fibrous. The glutinous matter being extracted, it will receive more tar than hemp, prepared in any other way. The quality may be more effectually tested by making ropes of an equal size or weight of that and other best samples of hemp, and bury all together in mud and water for any proper length of time; when taken up and put to the test, the result will fully show the difference in the quality of each kind of hemp.

Yours, respectfully,

THOS. H. BARLOW.

LEWIS SAUNDERS, Esq.,
Hemp agent for Kentucky.

PURCHASE OF HEMP.

We give below an interesting correspondence, which we find in the Democrat, as well as the remarks of that print; which are, perhaps, fair enough.

If hemp is to be purchased here at the west, there should be no delay on

the part of the government in making preparations for it. Let it be both inspected and purchased here, that the hemp-growers can receive their money, and have no further trouble about it, and they will be satisfied. No farmer will be satisfied with having his hemp pass inspection here, if he has to be at the further trouble of taking it around to Boston to be sold. Every farmer knows too much about the tricks of politicians and the tricks of trade to run any such risk.

Although Mr. Saunders, in his letter to the Democrat, says "that purchases will hereafter be made in the west," it will be seen that Mr. Bancroft, neither in his previous letter, which we have published, nor in this one, authorizes, except by inference, such a conclusion. The Democrat says:

"The reader will see, in another column, a communication from Mr. Saunders. This gentleman is indefatigable in his exertions to secure to the agriculturists of the west the advantages to which they are entitled. We congratulate him on his success. The Secretary of the Navy has given the subject his prompt attention. For the former arrangement of inspecting hemp at Charlestown, Mr. Bancroft is not responsible. As soon as he had time, he gave the subject the attention its importance demanded, and set the matter right. Let the same justice be meted out to the west in other things, and we shall feel the benefit of it."

—

GRASS HILLS, *August* 6, 1845.

The hemp-growers of Kentucky will see, by the annexed letter from the Secretary of the Navy, that the order directing the final inspection of hemp to be made at Boston has been rescinded, and that purchases will hereafter be made in the West.

The full supply of suitable hemp for the navy of the United States now devolves on the farmers themselves. The soil and climate of many parts of Kentucky are well adapted to its culture; the natural strength of the hemp is not surpassed by the production of any country. Have the hemp rotted in water of a *uniform* temperature, (not *overdone*,) then thoroughly cleaned; it will come up to the navy standard, and, after supplying the government, be sought after for the commerce of the world.

LEWIS SAUNDERS.

NAVY DEPARTMENT, *July* 29, 1845.

SIR: Your letter of the 21st instant has been received. The suggestions you offer, that a quantity of water-rotted hemp be advertised for, so as to give notice to the farmers in season to prepare it, will be fully considered at an early day.

Not being able, after reflection, to concur fully in the propriety of the order which directed that the final inspection of hemp must be made at Boston, I have caused that order to be rescinded, and the inspection made hereafter at the agencies in the west will be conclusive. In thus dispensing with the second inspection, I feel desirous to impress upon you the necessity of vigilance in the discharge of your official duties. If an inspection at the west shall be found efficient and safe, not only will this change have been justified, and the action of Congress upon the subject approved, but

the hemp-growers of that region must necessarily feel the benefit in future of an extended market, and an increased demand for their valuable staple.

Very respectfully, your obedient servant,

G. BANCROFT.

Lewis Saunders, Esq.,
Hemp agent, Louisville, Kentucky.

From the Dollar Farmer.

TO HEMP-GROWERS.

The following is from a source entitled to full confidence, and will attract the attention not only of the hemp-growers of Jefferson county, but of all others throughout the country:

To the Editors of the Louisville Journal and Dollar Farmer:

Gentlemen: I hope that what I write may be seen by the hemp-growers of Jefferson county, that they may read it, and that they may not sneer at it as the production of a city farmer, but that they may be profited by it.

By the present mode of growing and preparing hemp in this county, it is almost worthless for cordage and all the finer uses to which hemp is applied; it is not worth, in any of the eastern markets, as much by thirty dollars per ton as if it were properly prepared; and for bagging and rope, which is the coarsest use to which it is applied, it is not worth as much by fifteen or twenty dollars per ton as the hemp grown about Lexington and Maysville. For illustration, I will state that fair handled hemp will yield sixty or seventy pounds of clean hemp from each hundred weight; very ordinary hemp will yield forty-five or fifty pounds suitable for bagging; and a fair average of Jefferson county grown hemp will not yield over thirty-five or forty pounds from a hundred weight.

This great difference in value is attributable to the following causes: *First.* The land is not sufficiently pulverized before the seed is sown, and thus it comes up irregular, and produces a coarse, bark-like lint. This can be easily prevented by a liberal use of the harrow and roller. *Secondly.* In the process of cutting, they "gather" with the hook, and thus hack or partly cut asunder the lint on almost every stem, which is the chief cause of so much tow being made in the process of hackling. This mode of "gathering" the hemp with the hook is not practised anywhere in the United States except in Jefferson county. It is easily prevented: it only requires determination on the part of the farmer that his negroes shall not do it; and could they be made sensible of the loss they sustain by it in the depreciated value of their hemp, I am sure they would not longer permit it to be done. I would also suggest that they use the crooked hook, which is used in all the other counties of the State—at least, that they will try it before rejecting my suggestion. I am sure that a hand will cut one-third more per day than with the straight hook, and that he will do it better; and more by far than both these, they will avoid this destructive practice of gathering with the hook. *Thirdly.* It is common in this county to plough the ground before the hemp is spread upon it to rot; thus many stems are imbedded in the mud and become black-rotted—indeed, all the hemp is seriously injured and lessened in value by the mud. This can be prevented by having the hemp cut close and smooth to the earth, so the hemp for rotting can be spread upon it; or, if

this cannot be done, let a heavy roller be passed over the ground to mash down the stubbles. *Fourthly.* When breaking the hemp, they pound it too much with the brake, instead of ejecting the choves, after being thoroughly cracked with the brake, by whipping the hemp across the brake; their object is to leave in as much tow as possible, on account of weight; but a little observation and calculation will show this to be false economy. How much tow can they possibly leave in the hemp, and yet eject all the choves? Say twelve pounds in the hundred weight. Any bagging manufacturer will pay more than this difference, if this twelve pounds of tow had been whipped out; with hemp at three dollars per hundred weight, it is only thirty-six cents, or seven dollars and twenty cents per ton. At any eastern market, where hemp is chiefly wanted for cordage, a difference of fifteen dollars would be made. But I am well aware that the Jefferson farmers cannot venture to whip the hemp across the brake, so long as they permit their negroes to cut it asunder in the middle by gathering with the hook instead of gathering with the hand and arm.

I know that there are two or three farmers in Jefferson county who are exceptions to what I have said. As a citizen of Jefferson county, I would of course give the Jefferson farmer the preference in the purchase of hemp, at the same price, if of equal quality; but further I could not go, in justice to myself, nor will any manufacturer; but unless they will prepare their hemp as well as it is done in the other hemp-growing counties of the State, they must expect to take a less price for it. During the present season, manufacturers have been paying three dollars for hemp here, when, at the same time, they were paying three dollars to three dollars twenty-five cents, and bringing it one hundred and fifty to two hundred miles at their expense; and this is not the result of concert among them, for such is the competition to purchase hemp, that it always brings the last cent that the manufacturer can afford to pay; and even if it were concert, could not the same concert be as easily effected at Maysville, Lexington, Frankfort, and St. Louis?

A Manufacturer.

APPENDIX No. 9.

ON FLAX.

From the New York Farmer and Mechanic.

MEETING OF THE NEW YORK FARMERS' CLUB.

Chairman.—Our regular subject is now in order—the *culture and manufacture of flax and hemp* in our own country.

Judge Van Wyck.—I had hoped that our president would have been here to-day, and to have heard the result of his reflections upon the subject. I will make a few remarks upon it. I fear that the culture of flax will not repay the farmer if it is conducted as it has hitherto been done for fifty years past. Too much labor, too much cost in getting it prepared and sent to a proper market. The price of seven and a half cents to twelve and a half cents a pound will not remunerate the producer. The most which can ordinarily be raised, if for the lint only, is about four hundred pounds the acre; if raised for seed only, two hundred pounds. The capital employed, consisting of land, in our part of the country worth $100 per acre; animals and tools, $50; labor and dressing, and getting to market, altogether say $200. While the price will average but ten cents a pound, it will not remunerate the farmer. Perhaps on rich western lands it would pay, but not in our quarter, where grazing and raising of breadstuffs is far more profitable. Grain crops cost us nothing like the labor and expense of flax. Flax must be raised, puffed, housed, rotted, dressed, and got to market, with much delay and expense. You cannot persuade our farmers to raise flax unless you show it to be profitable; and they know what is for their best interest to produce. England had to abandon the culture of flax in favor of corn and cattle, although the government gave bounties by way of encouraging the flax culture. It will never do in the northern States, unless some revolution is effected in the culture, dressing, &c. If, by machinery, the difficulties can be overcome, then it may answer.

Dr. Underhill.—It is not intended to recommend the culture of flax after the old method, but on rich soil. When cut in the flower by a cradle, instead of hand-pulling, &c., this is an entirely new plan. We speak of the culture for the United States, and in the rich soils of the country west—Arkansas, &c. The crop of flax does not, when cut in the flower, impoverish land half as much as when allowed to go to seed, and gives a double crop of the flax; and so much finer is the fibre, that it is worth fourteen or sixteen cents a pound. The machinery of Billings can dress the flax for three cents a pound! and by cradling, rotting, and dressing in the manner Billings does it, almost twenty per cent. more of flax is made than was made by the clumsy old method; and the quality of the fibre far superior, silky, and beautiful. Hemp is peculiarly fitted for the rich lands of the west. I exhibit to the club a specimen of the Agave hemp, from Yucatan.

The lamented Dr. Perrine brought this article into notice. He was one of the most devoted friends of American agriculture that I have known. This hemp is the strongest in the world for ship's cables. But common hemp is becoming very interesting as a crop in our country. Forty-five

millions of pounds were raised here in 1844. A pamphlet issued by a distinguished citizen of Kentucky did greatly contribute to this most valuable result. Hemp is also now cradled when green.

Judge Van Wyck.—It is admitted in Europe that flax, although pulled when in the flower, yet exhausts land more than grain crops; but when it goes to seed it becomes a scourge to the soil. Not so with hemp, of which twenty crops in succession can be produced on the same land with but little manuring, and the last crop be perhaps a better one than the first!

Chairman.—One cause of the neglected culture of flax is cotton, so agreeable and so useful as apparel for the greater part of the year. As to hemp, there is no doubt as to our capacity to raise it; but I think that Mr. Clay must have a fine soil and well cultivated. I do not think that hemp is so great an exhauster of the soil as flax. * * * It is a difficult thing to fix dyes in linen; the colors, notwithstanding the use of the known mordants, are apt to wash out of linen.

Mr. Wakeman.—Linen may be made a substitute for cotton to a certain extent. We now import linen to as great an amount, or rather more than we did forty years ago, but not so much in proportion to population. We can raise say 448 pounds of flax per acre; Ireland raises upwards of 500. If ten cents a pound be the price, it is worth more than the cotton raised upon an acre. Everything in our country has been against linen. The duties began at 5 per cent. on sheetings, &c., then went up to $12\frac{1}{2}$. In 1812 they went up to $37\frac{1}{2}$ per cent. A great many manufactories of flax were commenced, and were operating extensively. The double duty and the war caused that. After the war the duty was 15 per cent., while upon cotton it was from 80 to 100 per cent. On woollen it was 25 per cent. In 1828 linen was 15 per cent.; hats, boots, &c., were at 30 per cent.

Had the same protection been extended to linen as to cotton, we should now be exporters of linen; now, that staple is all down. Our people must have proper inducement to go into the linen business, or they will never do it.

Flax is manufactured in Europe, into handkerchiefs, at 3,500 per cent. advance on its first cost.

Judge Van Wyck.—And cotton at 5,000 per cent.

Mr. Bergen, of Gowanus.—I have seen much flax raised. I do not think it is now a profitable crop. After the farmer has raised his flax, and even spun it into thread, he can buy his cotton thread cheaper than he can get his thread wove into linen. Flax is no greater exhauster of the soil than many other crops. He constantly looks for the greatest profit. Now, sir, it is said that if machinery shall be introduced, the profit will be got. It may be so; but how are we to get it? There are many ways proposed for the encouragement of flax and hemp culture and manufacture. But there is only one way; that is, to impose duties on the importation of flax. That is at the root of the matter: do that, and you will soon have a supply even for exportation.

Chairman.—I am for encouraging every profitable operation. No doubt exists as to the profit of raising flax on the rich lands of the west.

Mr. Wakeman.—With flax at 9 cents a pound, why cannot we manufacture linen? Linen keeps up in price, while cotton fabrics have fallen 75 per cent. Before long, probably, we shall prepare flax for $1\frac{1}{2}$ cent instead of 3 cents a pound, and improve in machinery. We ought not, at all events, to depend on foreign nations for that, or for any other necessary of

life. There is no land in Europe equal to ours for the production of flax and hemp, viz: the rich alluvial soil of the west.

Dr. Underhill.—We have much to do if we undertake to supply our own domestic wants, for we import now some millions. We now use cotton thread. The linen thread is much the best and strongest, and we cannot do without linen towels.

Mr. Fleet.—We have had specimens of manufactured linen from the household of Dr. Crispell, of Ulster county. He does it all in the old way, and the articles are very excellent. I agree that flax is peculiarly adapted to the rich soils of the western country.

Judge Van Wyck.—Flax is now admitted free.

Mr. Abbott.—In Ireland they pull flax after the leaves begin to turn yellow at the bottom of the stem, and after the flower is off, but before the seed has been matured.

Mr. Billings, of Missouri, was requested by the chairman to state his process of flax-rotting and dressing, and proceeded to state that for about three years past he has devoted himself to trials, and that his process differs very materially from the old methods. I pull or cut the flax green. We cut it now, having a proper cradle to do it with; a man cuts an acre in a day. I dry it in the shade. I rot it in water at 90 degrees of heat. The acetous fermentation takes place, and in three days it is rotted. I put it then in close rooms—heated until it is dry. It was said formerly that our flax was inferior to British, Belgian, or French; but when our flax is treated as I have stated, it is a superior article to any of them. I sow three bushels of seed per acre, instead of the old-fashioned one bushel.

Chairman.—In Cambray I remarked that they always put out their cambrics in the night time—always avoiding exposure to the sun; thus, as they said, preserving its fine appearance.

From the Cultivator.

BARLEY AND FLAX GROWN TOGETHER.

An experiment has been tried the past summer by some gentlemen of this town in raising barley and flax together, and has been attended with success, as appears by the following statements of Colonel Stibbins. He prepared an acre of ground for barley: after sowing two bushels on the ground, he then sowed one bushel of flax-seed on the same acre. In the fall he threshed the barley and flax out together with a machine, (it was cut and secured together,) and on cleaning it up he had 30 bushels of barley and 15 bushels of flax-seed. The sale of the crop stands thus:

Thirty bushels of barley, at 50 cents per bushel - - -	$15 00
Fifteen bushels of flax seed, at $1 per bushel - - -	15 00
	30 00

Colonel S. says the flax-seed was a clear net profit, as he thinks the ground produced as much barley as if no flax had been sown; for he had sowed barley on a few acres adjoining this acre, which produced only 30 bushels to the acre, and the land equally as good.

G. W. B.

Earlville, *New York*, 1846.

From the American Agriculturist.

CULTURE OF FLAX.

The following directions for the culture and proper management of the flax crop were compiled by the committee of the Society for the Promotion and Growth of Flax in Ireland. They have been carefully arranged from the mass of information obtained by the society and their agriculturists, during their four years' experience in the improved system of management. By this system, Irish flax has been produced which brought, in some cases, the high prices of £90 to £140 ($450 to $700) per ton. Messrs. Abraham Bell and Son, extensive shipping merchants of this city, have deemed them of so much importance that they have had them extensively published, and we transfer the same to our columns, esteeming it the most valuable article we have ever met on the subject. If the flax rotting and dressing machines spoken of in page 331 of this number perform all that is anticipated, the United States will be able to grow large quantities of it for the foreign market, which will be adding another important item to our agricultural exports, and greatly increase the wealth of the farming population. Formerly, considerable quantities of flax were grown in this State and New England; but since the introduction of cheap cotton fabrics as a substitute for linen, its culture has been almost entirely neglected. It is still grown extensively in Pennsylvania, Ohio, and parts of Kentucky.

Soil and rotation.—By attention and careful cultivation, good flax may be grown on various soils; but some are much better adapted for it than others. The best is a sound, dry, deep loam, with a clay sub-soil. It is very desirable that the land should be properly drained and sub-soiled, as, when it is saturated with either underground or surface water, good flax cannot be expected.

Without method, there cannot be success; different soils require a difference of rotation. In the best soils of Flanders flax is grown in the third year of a seven-course rotation, or the fifth of a ten-course rotation. It is not considered generally advisable to grow flax more frequently than once in ten years. In Belgium, it invariably follows a corn crop—generally oats; and in this country, where oats is such a principal crop, the same system might be profitably pursued; but it must be understood that it is only after oats following a green crop or old lea, and never after two or three succeeding crops of oats, which bad practice still prevails in some districts. It is a very general error among farmers to consider it necessary that flax should follow a potato crop. Except on very poor soils, a better crop will be produced after grain, and the double benefit of the grain and flax secured. If old lea be broken up, and potatoes planted, a very fine crop of flax may be obtained in the following year.

Rotation of crops for flax.—The following rotation, which would bring flax once in ten years, has been proposed: First year, potatoes; second, barley, laid down with grasses; third year, cut for soiling; fourth year, pasture; fifth year, flax; or the one half might be better in flax, the other in oats—so that, with the return of the rotation, which would be in five years, the flax could be put on the ground which, in the last rotary course, was under corn, throwing a range of ten years between the flax crops coming into the same ground.

A gentleman of much practical knowledge recommends the following as being the most profitable: 1. Oats, after grass and clover. 2. Flax, pull-

ed in August; then ploughed and harrowed in two cwt. guano and two cwt. gypsum; then sown with rape. 3. Potatoes, or turnips, well manured. 4. Wheat, and sown in spring with clover and rye-grass. 5. Hay and clover. 6. Grazing. 7. Oats. 8. Flax and winter vetches; guano, as before mentioned. 9. Turnips, well manured. 10. Barley, sown with rye-grass and clover. 11. Clover and hay. 12. Grazing. 13. Oats.

Preparation of the soil.—One of the points of the greatest importance in the culture of flax is by thorough draining, and by careful and repeated cleansing of the land from weeds, to render it of the finest, deepest, and cleanest nature. This will make room for the roots to penetrate, which they will often do to a depth equal to one-half the length of the stem above ground.

After wheat, one ploughing may be sufficient on light friable loam, but two are better; and on stiff soils, three are advisable—one in autumn, and two in spring, so as to be ready for sowing in the first or second week of April. Much will, of course, depend on the nature of the soil, and the knowledge and experience of the farmer. The land should be so drained and sub-soiled that it can be sown in flats, which will give more even and much better crops. But, until the system of thorough draining be general, it will be necessary, after oats, to plough early in autumn. Throw the land into ridges, that it may receive the frost and air; and make surface drains, to carry off the rains of winter. Plough and harrow very early in spring; and again a month after, to bring the land into good tilth, and clean it thoroughly from weeds and roots. Following the last harrowing, it is necessary to roll, to give an even surface, and consolidate the land, breaking this up again with a short-toothed or seed harrow, ere sowing.

Sowing.—The seed best adapted for the generality of soils is Riga, although Dutch has been used in many districts of country for a series of years, with perfect success. American seed does not generally suit well, as it is apt to produce a coarse, branchy stem. If used, it should only be on deep, loamy soils. Select plump, shining, heavy seed, of the best brands, from a respectable merchant. Sift it clear of all the seeds of weeds, which will save a great deal of after trouble, when the crop is growing. This may be done by fanners, and through a wire sieve, twelve bars to the inch. Home-saved seed, grown from foreign, has been used in many cases with success. It is suggested that a small portion of the crop may be allowed to stand until the seed be fully ripe, and then pulled, and the seed preserved for sowing; but the seed saved from *it* in the following year should only be used for feeding, or sold for the oil-mills. The proportion of seed may be stated at three-and-a-half imperial bushels to the Irish or plantation acre; and so on, in proportion, to the Scotch or Cunningham, and the English or Statute measure. It is better to sow too thick than too thin; as, with thick sowing, the stem grows tall and straight, with only one or two seed capsules at the top, and the fibre is found greatly superior in fineness and length, to that produced from thin-sown flax, which grows coarse, and branches out, producing much seed, but a very inferior quality of fibre. The ground being pulverized and well cleaned, roll and sow. After sowing, cover it with a seed-harrow, going twice over it—once up and down, and once across or anglewise; as this makes it more equally spread, and avoids the small drills made by the teeth of the harrow. Finish with the roller, which will leave the seed covered about an inch, the proper depth. The ridges should be very little raised in the centre, when the

ground is ready for the seed, otherwise the crop will not ripen evenly; and when land is properly drained, there should be no ridges. The sowing of clover and grass-seeds along with the flax is not advised, when it can be conveniently avoided, as these plants always injure the root-ends of the flax. But carrots may be sown in suitable soils in drills, so that the person pulling the flax may step over the rows, which may be afterwards hoed and cleaned, and should have some liquid manure. A stolen crop of rape or winter vetches may be taken after the flax. Rolling the ground after sowing is very advisable, care being taken not to roll when the ground is so wet that the earth adheres to the roller.

Weeding.—If care has been paid to cleaning the seed and the soil, few weeds will appear; but if there be any, they must be carefully pulled. It is done in Belgium by women and children, who, with coarse cloths round their knees, creep on all-fours. This injures the young plant less than walking over it; which, if done, should be by persons whose shoes are not filled with nails. They should work also facing the wind, so that the plants laid flat by the pressure may be blown up again, or thus be assisted to regain their upright position. The tender plant pressed one way soon recovers; but if twisted or flattened by careless weeders, it seldom rises again.

Pulling.—The time when flax should be pulled, is a point of much nicety to determine. The fibre is in the best state before the seed is quite ripe. If pulled too soon, although the fibre is fine, the great waste in scutching and hackling renders it unprofitable; and, if pulled too late, the additional yield does not compensate for the coarseness of the fibre. It may be stated that the best time for pulling is when the seeds are beginning to change from a green to a pale brown color, and the stalk to become yellow, for about two-thirds of its height from the ground. When any of the crop is lying, and suffering from wet, it should be pulled as soon as possible, and kept by itself. So long as the ground is undrained, and imperfectly levelled before sowing, the flax will be found of different lengths. In such case, pull each length separately, and steep in separate pools, or keep it separate in the same pool. If the ground has been thorough-drained, and laid out evenly, the flax will be all of the same length. It is most essential to take time and care to keep the flax *even, like a brush,* at the root ends. This increases the value to the spinner, and of course to the grower, who will be amply repaid by an additional price for his extra trouble. Let the handfuls of pulled flax be laid across each other diagonally, to be ready for the

Rippling—Which should be carried on at the same time, and in the same field, with the pulling. If the only advantage to be derived from rippling was the comparative ease with which rippled flax is handled, the practice ought always to be adopted. But besides this, the seed is a most valuable part of the crop, being worth, if sold for the oil-mill, £3 per acre; and if used for the feeding of stock of all kinds, £4 per acre. The apparatus is very simple. The ripple consists of a row of iron teeth screwed into a block of wood. This can be procured in Belfast, or may be made by any handy blacksmith.* It is to be taken to the field where the flax is being pulled, and screwed down to the centre of a nine-feet plank, resting on two

*The best ripples are made of half-inch square rods of iron, placed with the angles of iron next the ripples; three-sixteenths of an inch asunder at the bottom, half inch at the top, and eighteen inches long, to allow a sufficient spring, and save much breaking of flax.

stools. The ripplers may either stand or sit astride, at opposite ends. They should be at such a distance from the comb as to permit their striking it properly and alternately. A winnowing sheet must be placed under them, to receive the bolls as they are rippled off; and then they are ready to receive the flax just pulled—the handfuls being placed diagonally, and bound up in a sheaf. The sheaf is laid down at the right hand of the rippler, and untied. He takes a handful with one hand, about six inches from the root, and a little nearer the top with the other. He spreads the top of the handful like a fan, draws the one half of it through the comb, and the other half past the side; and by a half turn of the wrist, the same operation is repeated with the rest of the bunch. Thus the flax can be rippled without being passed more than once through the comb. He then lays the handfuls down at his left side, *each handful* crossing the other, when the sheaf should be carefully tied up and removed. The object of crossing the handfuls so carefully after rippling, when tying up the beets for the steep, is that they part freely from each other when they are taken to spread out on the grass, and not interlock and be put out of their even order, as would otherwise be the case. If the weather be dry, the bolls should be kept in the field, spread on winnow-cloths, or other contrivance for drying; and if turned from time to time, they will win. Passing the bolls first through a coarse riddle, and afterwards through fanners, to remove straws and leaves, will facilitate the drying. If the weather is moist, they should be taken in-doors, and spread out thinly and evenly on a barn floor, or in a loft, leaving windows and doors open, to allow a thorough current of air, and turned twice a day. When *nearly dry*, they may be taken to a corn kiln (taking care not to raise it above summer heat) and carefully turned, until no moisture remains. By the above plan of *slow* drying, the seed has time to imbibe all the juices that remain in the husk, and become perfectly ripe. If it be taken at once from the field, and dried *hurriedly* on the kiln, these juices will be burnt up, and the seed will become shrivelled and parched, little nutritious matter remaining. In fine seasons, the bolls should always be dried in the open air, the seed threshed out, and the heaviest and plumpest used for sowing or crushing. The light seeds and chaff form most wholesome and nutritious feeding for cattle. Flax ought not to be allowed to stand in the field, if possible, even the second day; it should be rippled as soon as pulled, and carried to the water as soon as possible, that it may not harden.

Watering.—This process requires the greatest care and attention. River water is the best. If spring water has to be used, let the pond be filled some weeks, or months if possible, before the flax is put in, that the sun and air may soften the water. That containing iron, or other mineral substances, should never be used. If river water can be had, it need not be let into the pond sooner than the day before the flax is to be steeped. Place the flax in the pool in one layer, somewhat sloped, and in regular rows, with the root end uppermost. Cover with moss sods, or tough old lea sods, laid perfectly close, the sheer of each fitted to the other. Before putting on the sods, a layer of rushes or rag weeds is recommended to be placed on the flax, especially in new ponds. Thus covered, it never sinks to the bottom, nor is it affected by air or light. A small stream of water allowed to run through a pool has been found to improve its color. It will be sufficiently steeped, in an average time, from eight to fourteen days, according to the heat of the weather and the nature of the water. Every grower should learn to

know when the flax has had enough of the water, as a few hours too much may injure it. It is, however, much more frequently *under*-watered than *over*-watered. The best test is the following: Try some stalks of average thickness, by breaking the *shove*, or woody part, in two places, about six or eight inches apart, at the middle of the stalk; catch the broken bit of wood, and if it *will pull freely out, downward, for that length, without breaking or tearing the fibre, with none of the fibre adhering to it*, it is ready to take out. Make this trial every six hours, after fermentation subsides, for sometimes the change is rapid. Never lift the flax roughly from the pool with forks or grapes, but have it carefully handed out on the bank by men standing in the water. Spread on the same day it is taken out, unless it be raining heavily; light rain does little harm. If it cannot be spread, let it be set on end, or separated into small parcels, to prevent it heating in the heap. It is advantageous to let the flax drain for a few hours after being taken from the pool, by placing the bundles on their ends, close together, or on the flat, with a slope.

Spreading.—Select, when possible, clean, short, thick pasture ground for this operation; and mow down and remove any weeds that rise above the surface of the sward. Lay the flax evenly on the grass, and spread thin and very equally. If the directions under the head of rippling have been attended to, the handfuls will come readily asunder, without entangling. Turn it two or three times while on the grass (with a rod about eight feet in length, and an inch and a half in diameter,) that it may not become of different shades by the unequal action of the sun, which is often the case through inattention to this point. Turn it when there is a prospect of rain, that the flax may be beaten down a little, and thus prevented from being blown away.

Lifting.—A good test of its being ready to lift, is, to rub a few stalks from the top to the bottom; and, when the wood breaks easily and separates from the fibre, leaving it sound, it has had enough of the grass; also, when one stalk in fifty is perceived to form *a bow and string*, from the fibre contracting and separating from the woody stalk. But the most certain way is to prove a small quantity with the hand-break, or in a flax mill. In lifting, keep the lengths straight and the ends even, otherwise great loss will occur in the rolling and scutching. Tie it up in small bundles; and if not taken soon to be scutched, it will be much improved by being put up in small stacks, loosely built with stones or brambles in the bottom, to keep it dry, and allow a free circulation of air. Stacks built on pillars would be the best.

Drying—by fire, is *always pernicious.* If properly steeped and grassed, no such drying is necessary; but to make it ready for breaking and scutching, exposure to the sun is sufficient. In some districts it is put to dry *on kilns* in a damp state, and is absolutely burnt before it is dry, and the rich oily property of the flax is always greatly impaired. On this point the society can scarcely speak too strongly, as the flax is either destroyed or rendered not worth one-half of what it would be, if properly dried.

Breaking, or scutching—If done by hand, should be done on the Belgian system, which is less wasteful than that practised in Ireland. If by milling, the farmer will do well to select those mills in which the improved machinery has been introduced. The society would also recommend that the farmer should endeavor to have his flax scutched by a mill owner who pays his men by the day, and not by the stone, even if it should cost

him higher in proportion, the system of paying the scutchers by the stone rendering them more anxious to do a large quantity in the day, than to produce a good yield from the straw.

The Courtrai system.—This is the universal mode in the district from which the finest flax we receive is brought. As soon as pulled, the flax is stooked without binding it. The handfuls are set up, resting against each other, the root ends spread out, and the top ends joining like the letter A, forming stooking about eight feet long, and a short strap keeping the ends firm. In this way it will resist wind and rain well, and dry fast. In six or eight days it may be stacked in the field; the seed to be taken off at leisure, in winter; the flax to be steeped the following May—a system which possesses the advantages of affording the farmer the best season of the year for steeping and grassing, and a time of comparative leisure, when his attention is not called to the harvesting of other important crops. It has, in many cases, when tried in this country, proved highly successful; although in others it has failed, from want of experience, perhaps, in watering and grassing it. The treatment in this way has made the flax, in some cases, worth two or three shillings per stone more than part of the same crop steeped green. It is recommended that trials of this system should be made, in the first instance, on a small scale.

To avoid exhausting the land by growing flax.—It has always been urged against flax culture that it exhausted the soil; but this is not necessarily the case. If the seed be saved, and cattle fed upon the bolls, a valuable addition will be made to the manure heap, as perhaps the richest manure is produced by this kind of food. The putrescent water from the flax pools should be carefully preserved, and either used as a top-dressing for grass, or mixed with the weeds and other refuse of the crop, in a heap, to ferment. By these means almost all the matter abstracted from the soil by the flax crop would be returned in the shape of manure—the fibre being supplied by the atmosphere alone.

FLAX SOCIETY'S OFFICE, BELFAST, *January* 1, 1845.

ANSWERS BY MR. BILLINGS, OF MISSOURI, TO QUESTIONS IN THE N. Y. FARMERS' CLUB, ON THE CULTURE AND MANUFACTURE OF FLAX.

1st. What kind of soil shall I choose? and what manure?

Where there is most lime. On our best prairie land we add twenty bushels of lime to an acre: the lime should be first slacked. Use, also, good, well decomposed manure.

2d. When and how often and how deep shall I plough it?

Plough as soon as the crop is off the field in the fall—plough deep, and, if necessary, use the sub-soil plough, so as to plough 12 inches deep. Then, in the spring, plough four or five inches deep.

3d. When and how shall I sow the seed—broadcast, or in drills? and how many bushels to each acre?

As soon as the land is ploughed in the spring, harrow it lightly, and sow two and a half to three bushels of seed; then harrow well.

4th. How shall I keep the crop clean?

The crops keep clean of weeds by the close, thick growth of flax.

5th. How shall I gather the flax, and at what time?

Cut the flax with a cradle, having a scythe from eighteen to twenty-two inches in length. Cut as soon as the blossoms of the flax begin to fall.

6th. How shall I secure the crop when gathered? what quantity in a bundle?

Let the flax lie on the ground until it wilts. In fair weather it may lie there thirty-six hours. Wet weather must be avoided at this time, if possible. Bind up as much flax as a wisp of flax will bind in one bundle. Shock it on the field, so as to prevent wet from getting into it. Do not stack it. Leave it in the shocks for five or six days. When the weather is favorable, and it is about as dry as you would have your hay or oats, then house it.

7th. How long can I keep it before it is sent to market?

Fifty years! The flax is improved by keeping it a year. The gluten which is in it then dissolves more readily when you come to rot it.

8th. Is it worth my while to rot it on my own farm?

No; you cannot make so good a profit by doing it.

9th. Is it worth my while to have a machine for dressing the crop?

If you can raise two hundred acres of flax, then you can afford to rot and dress it. One hundred acres will not pay a sufficient profit.

10th. What is an average crop of flax in the United States per acre?

About two hundred pounds to the acre, if you let it all go to seed, but four hundred pounds if you gather it in the blossom. Ireland averages five hundred and fifty pounds an acre on one hundred thousand acres.

11th. Do you know how much it will cost to raise it per acre?

Twelve dollars an acre when housed.

12th. What is the cost of dressing it? How much can one of your dressing machines prepare in a day?

Three cents a pound, from the stack to the bale press.

One of my dressing machines, with seven men, will dress in one day six hundred pounds of flax; and so much less tow is made by it, that it saves twenty per cent. of the flax by my operation. And the same process answers for hemp. Flax, when rotted in water heated to ninety degrees of Fahrenheit, is done in three or four days. In raising flax, a part of a field should be sowed thin for the seed. Common Flemish and French dressed flax imported into England for forty years past brings them from four to eight hundred dollars a ton. This difference of value is owing to the difference of qualities, which are assorted.

Mr. Wakeman.—Can flax and hemp be grown for a series of years on the same ground; or is rotation necessary?

Mr. Billings.—I have known hemp grown on the same field perfectly well for twenty years in succession. The hemp crop is from seven hundred to nine hundred pounds an acre. I add lime to land for flax crop, but not for hemp. When flax is not allowed to go to seed, it does not exhaust the soil one-half as much. It exhausts about as much as the wheat crop. Our corn and wheat in Missouri certainly exhaust our soil. We have already found the necessity of deep ploughing and sub-soiling the land. It is better and cheaper, by four to one, to cradle flax, than to pull it by hand in the old way. We do not consider the rotting and dressing flax an unhealthy business.

Dr. Underhill, of Croton Point.—It is exceedingly important to establish the culture and manufacture of flax in our country. For the last twenty-five years Ireland has used the water-rotting process: they pulled their flax

before it went to seed. They have depended on the United States for their seed for the last half century. We supplied almost all their flax-seed for sowing. Dew-rotting is apt to weaken the fibre and render it less fine. They used to put their flax in still water, where it rotted in from seventeen to thirty days. Dew-rotting requires some three months. Some lay the flax on the snow, and let it remain until spring: a very bad plan. The flax is liable to great damage from cattle getting among it—it is very unequally rotted, and liable to become dirty: it loses its softness and fineness of fibre. The operation of cradling flax is an important one: you get rid of the roots of the plant, which are injurious in the dressing of the flax. I believe it would be profitable to raise flax, cut it in blossom, and water-rot it on the farm, at least until Billings's new plan can be found convenient to the farmer. Cotton is now whitening the ocean in the form of sails. Cotton is displacing linen in many ways. Our country is fast being filled with people: we must have profitable employment for all hands. We have climates for tea, coffee, grapes, plantains, bananas, yams, and every good thing, independent of the whole world. We must bring our country to that natural position to which it is entitled, and then I am for reciprocity treaties with all the world.

Mr. Billings.—We have exported some hemp to Dundee.

Edwin Williams.—We raise about forty thousand tons of hemp per annum.

Mr. Billings.—Fifty thousand.

Dr. Underhill.—In 1844, our western country raised about forty-five millions of pounds of it. They made the bagging and ropes for about two millions and a half bales of cotton. Two vessels loaded with our hemp left New Orleans for England last year, loaded with American hemp. The culture of hemp is increasing among us.

Edwin Williams.—In 1844 our import of cotton bagging was but one million six hundred thousand square yards. Many important articles of our trade are not well noted, or distinguished from masses, in our tables of import.

Mr. Meigs here read the following paper on the subject of flax:

The monthly committee meeting of the "Society for the Promotion and Improvement of the Growth of Flax in Ireland," was held on Wednesday at the society's rooms, Commercial Buildings, Belfast. The treasurer's report noted a receipt of £1,000 5*s.* since last meeting, 1st ult. A report of the sub-committee appointed to conduct the experiments on different kinds of flax-seed was read.

As the appearance of the flax grown from home seed is everywhere very fine this season, a paper was directed to be drawn up, for circulation among the farmers, urging them to reserve a portion of their growing crop for seed; letting it get ripe, and stacking it over until spring—the seed to be then separated, and the flax then to be steeped on the Courtrai system. This would do much to secure the genuine fresh seed for the crop of 1846. Arrangements were made for the opening of a hand scutching school in Youghal, where persons would be instructed in the Belgian mode, by one of the society's agriculturists. Several letters were read relative to flax-seed, &c., and referred to the sub-committee appointed to consult on the measures to be taken by the society to protect the farmer, in the most effective way,

against fraud in future seasons. The following extract from the letter of a gentleman in the county of Derry will prove interesting:

"I am happy to be able to bear my testimony to the fact, that if flax be judiciously grown, and well handled, there is no other crop that will pay like it. I had last season not quite 8 Irish acres of flax, from which I had 295 stones, which brought 8*s.* per stone in Cookstown market, and 31 stones at 6*s.*, besides $4\frac{1}{2}$ cwt. of scutching tow, at 9*s.* per cwt:

	£	s.	d.
295 stones, at 8*s.* - - - - - -	£118	0	0
31 stones, at 6*s.* - - - - - -	9	6	0
$4\frac{1}{2}$ cwt. tow, at 9*s.* - - - - -	2	0	6
	129	6	6

being upwards of £16 per acre. Besides this, I had an exceedingly large quantity of bolls, which fed my cattle to the greatest advantage during the whole season, and as much seed saved, on the Courtrai system, as sowed about three acres this year. The flax-seed saved on the Courtrai system turned out exceedingly well; and my steward showed some of the seed to Mr. MacAdam, of Donegall street, Belfast, who said that he thought it finer than any Riga seed he had seen last season. I may add, that the flax from our own seed looks to the full, better than that growing from Riga seed. We used but the two."

Mr. Meigs remarked, that the ingenious men of France and England had long been trying to make machinery to spin flax with the same facility as cotton; that the French chemists had carefully examined the fibres of flax, and discovered that the whole length of the flax is composed of delicate fibres, about three inches long, which, by means of chemical agents not injurious to that fibre, could separate it, and thus rendering it in staple nearly like cotton, and prepare it for the spinning machinery. When that can be accomplished with such economy that its price can be as low, or nearly so, as cotton cloth, there could be no doubt that for sheets, shirts, toweling, &c., mankind will far prefer the fabric of linen to that of cotton; and we would earnestly commend to the genius of our countrymen the invention of such process as can bring out that very valuable result; for in addition to the very well known preference for linen for many purposes, it is certain that flax grows well in vast portions of the globe where cotton cannot mature, for lack of heat, &c.

* * * * * * * * * *

Mr. Chapin.—On this subject I remark that the Chinese possess a grass called Chinese flax, which, from samples recently examined, appears to possess all the qualities of our flax, but in a higher degree, superior to any flax known or manufactured in England. This excellence consists in greater strength of fibre and fineness of staple, and length of staple also. Samples have been shown of fine linen manufactured from it, greatly resembling the French cambric, but having moreover a silky appearance. It seems also that this grass can be obtained in unlimited quantities. If these are facts, (and it would seem that they are,) it becomes an object of the greatest importance to our countrymen, as well as to Europe.

From a letter of Chas. L. Fleischmann, Esq., published in the Washington "Union," March 5, 1846.

AUSTRIAN LINEN MANUFACTURES, &c.

This branch of Austrian national industry is the oldest and one of the most important; but since cotton goods are coming daily more in use, it is declining in the same ratio as the cotton manufactures increase: it still, however, furnishes a greater number of pieces of various kinds, as well as all the other branches of a similar nature.

It is highly important for Austria that this branch of industry should rise again to its former importance, as it produces the raw material within its own territories, and especially in those regions where corn is an uncertain crop, and whereby the population obtain the means of procuring food and employment during the long winter season.

The yearly average crop is computed, according to official data, to amount to 1,500,000 cwt. of flax, and 1,000,000 cwt. of hemp.

The best flax is raised in Bohemia, Moravia, and Silesia; but its quality is not equal to that of Belgium. The farmer has not the proper knowledge of its culture, and less of the necessary manipulation in its preparation for the use of the spinner. The flax is generally prepared by dew-rot; and, from the following statement, the difference of quality between Austrian and Belgian flax (water-rotted) can be appreciated: 1 cwt. of Austrian flax, when prepared, yields 20 pounds of refuse, 50 pounds of tow, and only 30 pounds of flax; whereas Belgian flax gives 5 per cent. refuse, 20 per cent. of tow, and 75 per cent. of flax.

The yarn is almost all spun by hand. Austria has only eight flax-spinning factories, which have been in operation since 1835, and employ 20,800 spindles; England has now 700,000 spindles; France, 70,000; Belgium, 60,000; the countries in the German league, 30,000.

Flax spinning by means of machinery has been brought in England (like all other mechanical contrivances) to great perfection; and from thence Austria has procured her machines. The amount of capital required for such a factory is nearly eight times higher than for a cotton factory, on account of the complicated machines required for spinning flax.

A spindle is estimated at 80 to 100 florins, inclusive of building and other necessary apparatus; a cotton factory at 12 florins.

Weaving is also generally done by hand. The number of looms engaged in this branch amounts to 300,000, which occupy 500,000 weavers during the greater part of the year; about 12 spinners are necessary to supply a loom with yarn, which occupies about three and a half millions of persons in the linen business, or one-tenth of the whole population.

The above-stated number of looms produce yearly 4,600,000 pieces of linen, of 30 ells (yards) each, valued at 27,000,000 florins.

The following table shows the import and export of flax and linen in the year 1841:

	Imported.	Exported.
Flax	15,056 cwt.	25,199 cwt.
Yarn	20,902	5,701
Thread	209	1,926
Fine linen	8	1,722
Coarse linen	838	49,012
Various other linen goods	1,055	52,660

When the above table is compared with those of former years, it shows a great increase in the importation of yarn, which arises from the greater perfection of the English flax-spinning, which has produced such fine numbers as are unattainable with their less perfect machinery.

The following data are from the largest factories of Austria:

100 pounds of unprepared flax cost 20 florins, which yield 20 pounds of refuse, remainder 80 pounds - -	20 flor.
From this 80 pounds of flax are obtained, in hatcheling, 50 pounds tow, cost 10 florins per cwt. - - -	5
Remain 30 pounds hatcheled flax, at 50 florins per cwt. -	15
The wages for swingling, 34 kreutzers, and hatcheling, 46 kreutzers - - - - - - -	1 flor. 20 kr.
30 pounds of hatcheled flax cost, then - - - or $32\frac{2}{3}$ kreutzers per pound.	16 flor. 20 kr.
1 piece of yarn of the average, No. 45, weight $23\frac{1}{2}$ loth, or about 12 ounces, costs - - - - -	24 kr.
Which produces, in spinning, $12\frac{1}{2}$ per cent. refuse - -	3
Cost per piece - - - - - - -	27
Add to this the yearly expenses of repair, assurance, &c. -	13 84-100
Interest on the capital - - - - - -	3 50-000
Of this sum $22\frac{1}{2}$ kreutzers is for the material, and 21 84-100 kreutzers for the expense of spinning - - -	44 34-100

APPENDIX No. 10.

From the Albany Cultivator.

TOBACCO.

Messrs. Gaylord & Tucker: We grow in this town annually about three hundred tons of tobacco, and in the valley of the Connecticut about five hundred tons are grown annually. The yield the last year (1843) was less than usual, fifteen hundred pounds being about the average per acre. The price of tobacco the last season, of a fair growth, was seven cents a pound, and most of the crop was sold before housed and cured. We have two varieties of the weed, the broad leaf and the narrow leaf—the latter is about two weeks the earliest.

It seems our tobacco is of a peculiar species, or our soil and climate are peculiarly adapted for the production of a superior article.

The soil that produces our best tobacco is a light sandy loam. We prepare our beds for the seed as early in April as possible—select the richest or best land in the garden or on the farm, moist but not wet—manure and prepare it as we do for the cultivation of cabbage or any delicate plant for transplanting—pulverize and make the bed as fine and smooth as possible; then sow the seed broadcast, about as thick as we do cabbage seed; then roll or tread down the bed thoroughly, that the seed may be *pressed* into the soil. The bed is kept clean of weeds. In a common season the plants will be large enough for transplanting by the 10th of June. The land for the crop should be well manured, and ploughed at least twice before the time of transplanting, and harrowed and rolled, or bushed, and left as smooth as possible. We mark the rows three feet apart and straight; on the rows we make small hills for the reception of the plants, two feet to two feet six inches apart. We have our land all prepared by the time the plants are large enough for transplanting. If raining at the time, we take the advantage of it and get all our plants out; if not, we set and water. After this, the field is examined several times, and where plants are dry, or injured by worms, others are set in. As soon as they stand well, they are carefully hoed and vacant places filled with new plants; after this the cultivator is used between the rows and the crop kept clean with the hoe. The plants are frequently and thoroughly examined for the tobacco worms, and they must be destroyed; if not, the crop is sure to be. When in blossom, and before the formation of seed, it is topped about thirty-two inches from the ground, leaving from sixteen to twenty leaves on each stalk. After this the suckers at each leaf are broken off, and the plants kept clean till cut. When ripe, the time of cutting, the leaf is spotted, thick, and will crack when pressed between thumb and finger. It is cut any time in the day after the dew is off, left in the row till wilted, then turned; and if there is a hot sun, it is often turned to prevent burning; after wilted, it is put into small heaps of six or eight plants, then carted to the tobacco sheds for hanging. We usually use poles or rails about twelve feet long; hang, with twine, about forty plants on each rail—twenty each side—by crossing the twine from the plants one side to the plants the other, the rails about

twelve inches apart. It hangs from six to ten weeks to get perfectly cured, which is known by the stem of the leaf being thoroughly dried. It is then, in a damp time, when the leaves will not crumble, taken from the poles and placed in large piles by letting the tops of the plants lap each other, leaving the butts of the plants out. It remains in these heaps from three to ten days before it is stripped, depending on the state of the weather, but must not be allowed to heat. When stripped, it is made into small hands; the small and broken leaves should be kept by themselves. It is then, by the purchaser, packed in boxes of about four hundred pounds, and marked *seed-leaf tobacco.* The most of our last crop has been shipped to Bremen.

I think we can cultivate one acre of tobacco with the same labor and expense that we can two acres of corn, that produce sixty bushels to the acre; and the manure required is about the same as for the corn crop, and I do not think it exhausts the land as much as the corn crop, for it is not allowed to seed.

HENRY WATSON.

East Windsor, *January* 22, 1844.

Prospect Hill, *April* 26, 1844.

Dear Sir: Your favor of the 26th of March was duly received, and would have been sooner answered, but that I desired to obtain some information on the subject of your inquiry, from some of my friends in the tobacco-growing region of Mason county. I had occasion to take a ride through that part of the county two days since, and met with some intelligent tobacco growers, with whom I conversed freely on the subject. I was formerly engaged in the tobacco culture, but have for a number of years discontinued its culture; and was, therefore, desirous of availing myself of any late improvements which might have been made. For the general mode of treating the tabacco crop, from the sowing of the seed till it is prepared for prising, I refer you to my essay on that subject, published in the Kentucky Farmer in March, 1841, and which will be re-published in a volume of agricultural essays, now in press, and which will be ready for delivery in about two months, a copy of which I will do myself the pleasure of sending you. In this letter I shall attempt to give you such additional information as may be useful in producing the fine tobacco cultivated for cigar wrappers.

1. With respect to the kinds of tobacco cultivated for the above purpose. There are the Summerville and light Burley: some prefer the former, and some the latter. I do not understand that either has a decided preference.

2. As to the soil suitable for its growth. Fine tobacco is found to succeed best on light rich soil, having a portion of sand mixed with it. New or fresh land is better than old; and pretty steep hillsides, provided they are light and rich, are better adapted to producing fine tobacco than level land. Hillsides, facing the Ohio river, and the numerous small branches emptying into it, when the land is newly cleared, and sufficiently rich, are well adapted to produce fine tobacco. I have seen these in cultivation, having an elevation of from twenty to thirty degrees. But level lands, or

those nearly so, if new, and especially if the soil have a mixture of sand, are also well adapted to produce fine cigar tobacco.

3. As to the mode of cultivation. This, perhaps, is the most important point in producing fine cigar tobacco. The ground should be well prepared, and rendered as light and as finely pulverized as possible. In laying off for planting, I would advise the use of a single horse plough, throwing the ground into ridges three and a half feet from centre to centre, and then crossing, at right angles, with single furrows, at the distance of two feet from centre to centre, and make the hills, so as to be as near a true line as possible, three feet and a half from centre to centre one way, and two the other. I recommend the use of a one-horse plough in laying off, because in this way the ridges will be but little trodden down, and the ground will be left in a light condition. The difference in the width of the rows is to facilitate the working of the tobacco after it attains some size.

Close planting is found to be essentially necessary in raising fine tobacco. In the above mode of planting, each plant occupies seven square feet; and six thousand two hundred and twenty-three plants will stand upon an acre, if none be missing; and, allowing four plants to make a pound, the yield will be one thousand five hundred and fifty-five pounds per acre. I have heard of instances in which the product has been at the rate of a pound for three plants, or more than two thousand pounds per acre. But to produce this extraordinary crop, the season must be very favorable, and everything be managed in the most particular and skilful manner.

To make fine tobacco, it is very important to plant *early*, so that the tobacco may be cured at that season of the year when the weather is warm and dry. To this end, plant-beds should be sown very early and in situations where they have a good southeastern exposure. They should be lightly covered with brush to keep them moist until the plants get up, and a little while longer if there is danger of hard frosts. New ground is best for plant-beds. The hills for planting should be made as recently before the plants are ready as possible. These may be set out when very small, if the operation be skilfully managed, and thus the crop will be brought forward in good time. The plants should be topped to about sixteen leaves, exclusive of the ground leaves, which should be broken off. The top leaves will, of course, not make fine tobacco, and must be separated when stripping; but high topping is important to improve the quality of the first ten or twelve leaves on each plant.

It is the practice in Mason to cure tobacco without firing, except in damp rainy weather, when fire is applied to guard against what is called *house-burning*, the danger of which is always increased in rainy weather, especially where tobacco is hung close. The almost universal mode of building tobacco houses in Mason is, to erect a four-square pen of logs, hewed or round, with large open spaces between them, and then to construct a shed all around, about twelve feet wide, by planting posts in the ground, (locust if to be had,) and ship-lapping scantling on these, at proper distances, from which poles are extended to the cracks of the log pen. The shed should be planked up and down, to protect the tobacco from the weather. For the benefit of air, small interstices may be left between the planks, and it would be advantageous to have some broad planks, hung on hinges, on every side of the shed, which might be opened in dry weather for the purpose of ventilation. It is now too late to sow tobacco seed, but, if you wish it, I will procure and send you some in time for next year.

I have given, in answer to your inquiry, what seemed to me to be necessary. If you wish further information on any particular points, it will afford me pleasure, at all times, to comply with your wishes.

Yours, cordially and sincerely,

A. BEATTY.

To George W. Weissinger, Esq.

From the Floridian.

MODE OF CULTIVATING TOBACCO IN THE ISLAND OF CUBA.

Your nurseries are the first to be attended to, in your preparation for a crop, by selecting, at the proper season, a rich and tolerably moist piece of new ground, and prepare it by burning it off very clean, and breaking it up. The seed is then to be sown broadcast upon it, and when they are up they are to be overlooked daily, to see that the cut-worm does not commit ravages among the young plants; and as fast as the plants arrive at a proper size, they are to be transferred to the tobacco field, to make room for the smaller plants of the nursery. As casualties frequently arise to destroy some of the nurseries, it is necessary to guard against a probability of not having a sufficient number of plants, by making three or four nurseries, at an interval of one or two weeks each. Much attention should be observed to keep both your nurseries and fields very clean, particularly of grass, and for that reason new lands are preferred for both. In Cuba they plant on an even surface, and disturb it as little as possible with the hoe, only picking out the grass or weeds which spring up. The plants, when transferred to the field, are to be planted in squares, at about from two to three feet apart, according to the strength of the land. The high lands in Cuba are such as produce the quality of tobacco, both as to strength and color, that suits the American market best, and such lands correspond nearest to our high hammocks. The greatest enemy to the plants, both in the nursery and in the fields, (while small,) is the cut-worm, which has to be looked after early every morning; and wherever they have eaten the plants, they are to be found and killed, either on the plant or on the ground near it. When the plants get to be larger, then the large green tobacco-worm is to be constantly guarded against, and the suckers also continually broken off as fast as they appear; and when the tobacco is judged to be of a sufficient height, it is to be topped and allowed to mature for cutting. The time of maturity is ascertained by the leaves changing gradually their color, beginning at the bottom leaves, from their deep green growing color, to a yellowish green; but if this is not sufficiently obvious, and you deem your tobacco ripe, you may test it by crushing together the tip of any of the upper leaves, which, if it snaps, is a sign of its being ripe; but, on the contrary, if it does not snap, it is not fully matured. When ripe for the knife, it is cut down near the ground, leaving two suckers, which have been spared a week or two prior, ready to grow up and produce a second crop; and also a third crop may be realized in the same manner. The tobacco is to be conveyed carefully, in wide thongs of cowhide, to the house, to be hung up—a shed is preferred, with free space for ventilation beneath; and after tying the plants together, two to each string, and leaving space enough between them to insert a wooden peg, you hang them up by intruding them above each

rafter up to the ridge of the house, being careful not to hang them so near that they will touch or crowd each other in drying, or your tobacco will mould. Also, when the weather is moist you must make small fires enough under it to keep out the moisture, but not enough to heat your tobacco. When the leaves are perfectly dry, the whole are to be taken down and placed in a press for a few hours, the object of which is, if the tobacco is too dry to strip off without breaking the leaves, that they may become soft and pliable; but great care must be taken that it does not heat; and it must be strictly examined, by inserting the hand, to ascertain that it becomes not too hot. The press is made by putting rails or poles crosswise of each other, in form of a rack, and placing cowhides under, over, and around the tobacco, and placing upon it something somewhat weighty. It is then to be stripped leaf by leaf from the stock, and, being selected, the wrappers from the fillers, to be tied at the butts and prepared for market. It is sometimes usual to put it again in press after being stripped.

From the American Agriculturist.

CULTURE OF TOBACCO.

The growing of tobacco is becoming an important business in the valley of the Connecticut, and yields a better return to the farmer on rich land than almost any other crop. This crop was greatly increased the last season, and I think I do not exaggerate when I estimate the amount grown in the towns bordering on the Connecticut, between Hartford and Northampton, from 1,500 to 2,000 tons. The price the last season, for large growth, and in good condition, was eight cents per pound. We have two varieties—the narrow and the broad leaf. The latter is the most productive, and sells in market much more readily than the former.

Soil, preparation, and sowing.—We select for our tobacco plants a rich, moist (but not wet) spot, and sow the seed as early in April as the ground can be prepared for it. Our beds are well manured, made mellow and fine, and the seed should be sowed at the rate of one table-spoonful to the square rod, before the earth gets dry; after this it is raked, so that the dirt may stick close to the seed. It should not be covered, but let a man go on and tread the surface of the bed as hard as possible. The bed must be kept free from weeds. The plants should get leaves two or three inches long before being transplanted. They grow faster in the beds at first than in the field, and are less exposed to the cut-worm.

Transplanting.—We commence transplanting the fore part of June, and often set out the plants as late as the 20th or 25th. The ground should be made mellow and level. The broad leaf plants should be set in the rows two and a half feet distant from each other, and the rows be three feet four inches apart. If it rains at the time of setting, we take advantage of it, and get out as many as possible. If not, we make the hills, and pour into each about half a pint of water, and follow immediately after and set the plants. They will live as well, set in this way, in sunshine as in the rain. The ground should be looked over two or three times afterwards, and re-set the vacant plants.

After-culture.—As soon as the plants are well growing, we go through with the cultivator, and again fill up the vacant places. The crop

should be hoed three or four times without hilling the plants. When the green worms appear, they must be watched and killed, or they will in a great measure destroy the crop.

Topping.—Commence topping the tobacco when it is in the bloom, and manage to top as much as possible the first time going over, that it may all ripen at once. Leave about twenty leaves to the stalk, and make the field as even on the surface as possible. If you have late plants in consequence of re-setting, break them low, and they will grow faster and ripen sooner for it. The suckers should all be broken off and the plants kept clear of weeds till they are cut.

Cutting and curing.—We should never cut more than can be hung the same day and next morning, while the dew is on. After cutting, it should lie and wilt on one side, then turn it and wilt the other; then throw it into heaps of six or eight plants each, and let it lie till carted to the sheds, where it is hung with cotton twine on poles twelve feet long, and about twenty plants on each side. It must hang till the stem of the leaf is thoroughly cured to the stalk. It is then taken down in a damp day, (to prevent the leaves from crumbling,) and stripped and tied in three small hands, keeping the broken and poor leaves by themselves. It is then packed, and pressed hard with the hands, in a double row, with the butts out, and if not sufficiently cured in a few days, it must be shaken up and re-packed, to prevent heating. When fit for market it is brought in large quantities and pressed in boxes containing about four hundred pounds each, and sent to the seaports and shipped to foreign countries.

Value of poudrette.—I used one barrel of poudrette on my plants while on the bed, leaving a small piece without it. The effect was astonishing. The plants at the time of setting were twice as large where the poudrette was used as where it was not, and they were not as much attacked by the worms, which is an important consideration. I set the last season about two and a half acres in tobacco, which produced 5,100 lbs. I sold it for $408.

P.

South Hadley Falls, Mass., *March* 3, 1845.

We had the pleasure of visiting our intelligent correspondent above, last year, and saw his tobacco crop growing. We recently met with an enterprising farmer from Windsor, who estimated the crop grown the past year in the valley of the Connecticut and its vicinity at 5,000,000 lbs. He said he could get from 12 to 16 cents per lb. for his; and although it was used for a different purpose, he did not know why it was not as good as the Cuba, which sells from 25 to 35 cents per lb. Prime tobacco land rents high at present in the valley of the Connecticut—from $25 to $50 per acre per annum. A rich, friable, loamy clay is considered the best soil for this crop, which must be highly manured, and deep and well worked. We think it ought to be sub-soil ploughed, and that guano as well as poudrette would be an excellent manure for it. The latter is the most lasting, and is said to keep of the fly. Coarse barn-yard manure makes too rank a growth of stalk and leaf, and injures the quality of the tobacco; whereas poudrette, guano, and other fine and highly concentrated manures, would add to its aromatic flavor. We should be glad to see carefully conducted

experiments made the present season with these manures, on the tobacco crop. The different kinds might be tried side by side on separate rows, with a view of testing which was best for that particular locality and kind of soil. We should be pleased to learn whether the culture of the finest Cuba tobacco has ever been attempted in New England. This is frequently worth from 50 cents to $1 per lb.—*Ed. Agriculturist.*

From the N. Y. Farmer and Mechanic.

As the growing of tobacco is receiving attention, and is raised to good profit, I must give you an estimate of the cost to raise one acre, made by myself, with the help of friend L.; and he should know, as he has several acres which average one ton per acre, and sells at Warehouse Point for 8 cents per lb.—$160 per ton. Mr. L. says one ton per acre is a good crop; and probably more falls short than comes up to it. Now for the estimate:

Use of one acre of land, one year			$15 00
10 carts of manure, at $2 50	$25 00	one-half is	15 00
Carting and spreading	5 00		
Ploughing twice			3 00
Harrowing and marking			1 00
7,000 tobacco plants, sold at 50 cents			3 50
Holding and setting plants			3 00
Hoeing four times			5 00
Extra attendance to secure and kill worms			2 00
Topping and securing			4 00
Cutting and hanging up to dry			4 00
Stripping from stalk and packing			5 00
Rent of shed to dry in			4 00
Freighting to Warehouse Point			3 00
			67 50

Now $67 50 from $160 leaves a net profit of $92 50 per acre. What crop other than tobacco would make so good return? This is a fact worthy of consideration.

From the Southern Planter.

TOBACCO PLANTS.

Mr. W. W. Gilmer, of Albemarle, is so notorious for his uniform success in raising tobacco plants, that we were requested to obtain and publish his method of managing his beds. To an application to that effect, we have obtained the following answer:

"My Dear Sir: My plan for raising tobacco plants is the result of careful observation and inquiry for twenty years. All planters of common intelligence are able to pick the best location on their estates for plants; most of them are aware that some moist and some dry land should be prepared. I burn half in situations where water may be carried round in ditches—the balance on high ground. Early and hard burning all know to be best; yet many persons put off the evil day, and *scorch*. The land should be

made red-hot if possible, for at least two inches. We frequently chop with a grubbing hoe before burning, regulating the depth according to the soil; prepare the beds as soon as burnt; sow half the seed the middle of February—balance middle of March, on each bed; never put more than two-thirds of a spoonful of seed to the one hundred square yards. Many beds have more good-for-nothing plants left, after their owner has failed to pitch, than would have planted double his crop. By sowing at the periods mentioned, we avoid usually the danger of having the young plants thrown out by frost, and get as good roots as when sown in December or January.

"After the March sowing, cover the beds from one-eighth to one-fourth inch thick with chaff which has been used for bedding in stalls for several months; put in at first six or eight inches, and keep the horses well littered with it; about February take it out, and put it in a pen well sheltered. First of March take it to some clean floor, and beat it fine with a flail, then sow, fifteenth March, from hampers. The stalls should be plastered at least once a week freely, (farm pens also.) Cover the beds with brush as usual.

"I had this year a fine bed in an old field which had grown up, and never had more or better plants.

"The horses littered with chaff should be fed on corn and fodder, or some food clear of grass seed. The chaff manure is Dr. Gantt's idea, and I think it a long way ahead of guano and every thing else.

"We never move the wood. Burn out the bed at a single fire; put down large pieces to keep the wood from the ground, &c.

W. W. GILMER."

For the Southern Planter.

THE SPOT IN TOBACCO.

Mr. Editor: If any among the many who write for the Planter have found any means to prevent the spot in tobacco, or to stop it after its appearance, you would be doing us great service in this section of country to publish it in the Planter. Perhaps you have done it heretofore; if so, please give it another insertion for the benefit of your new subscribers. If the matter has not been discussed already, be so good as to call the attention of your contributors to it. We would like to find out pretty soon, as the season for tobacco to spot is just at hand. Your attention to this matter will very much oblige

Your humble servant,

JESSE J. KELLY.

Granville County, N. C., *July* 31, 1845.

We have published many valuable communications on the subject of tobacco, but none have met with more general approbation than those from the pen of Mr. N. A. Venable. Upon this important subject of the *rot*, he says:

"Passing over the time of planting, priming, topping, &c., on which our writer is sufficiently explicit, we come to the *casualties* or *diseases* to which the crop is subject. The first mentioned by our writer, and by far the most serious, is the spot or firing, or more properly the rot. This is caused by too much rain, and is more liable to occur on sandy soils, and less so on

those that are stiff, red, or thirsty. It is of much rarer occurrence of late years than it was formerly, which is ascribable, doubtless, to the improvements in management and cultivation which experience has suggested. The mode formerly practised was to cultivate the crop almost level, and to keep the soil between the hills loose and well broken; under this mode of cultivation, immense losses were sustained almost yearly by fire. But by adopting just the reverse of this, by scraping up carefully with the hoe all the loose earth among the hills, as deep as the plough has gone, and throwing it on the hills, and leaving the ground among the hills as hard, if possible, as a path, the leaves of the plant, when it is large enough to take the rot, will shield the hill from the rain, and throw the water off on the hard ground, which soon runs off, and the crop is protected. A sufficient quantity of vegetable matter turned into the soil will also do much towards preventing this disease. This is proved by the well-established fact, that the first crop on a clover and herdsgrass fallow, where the land is very sandy, does not fire, whereas the second or third are almost certain to do so, unless some vegetable substance is turned into the soil; and hence such land (sandy loam, river or creek flats) should not be cultivated two or three years in succession, let them be ever so rich, without applying some vegetable matter or other. These are matters of the greatest importance, for there is no disease more destructive to the tobacco crop than the one we are considering; and I verily believe, if we could have cultivated our crop last year in this way, as unfavorable as the season was, we should have escaped the disaster. But the summer was so unusually wet, we were unable to cultivate our crop in our usual way, and it is the first time we have suffered with the disease. I would not be understood to say that it can always be prevented, but I do believe that it can be generally done, and in the way I have above indicated. I will only add that I very much question the propriety of ever ploughing the crop after the plants have got large enough to take the rot, on account of the loose earth that is thrown up."

Upon these remarks of Mr. Venable appeared the following commentary, in the May number of the Planter for 1843. We should be pleased to hear the subject further discussed:

Messrs. Editors: I have been reading with much interest the several communications upon the cultivation of tobacco from the pen of Mr. N. A. Venable. I have been struck with some of his positions with regard to the mode of cultivation to prevent fire, (or rot, as he terms it.) The cause to which he attributes it—that is, too much rain—I think correct; but to prevent its ruinous consequences, I resort to precisely the opposite course, namely, ploughing deep and thoroughly, so as to admit the rapid absorption of the water, which by his mode will either be altogether prevented or effected only at the expense of a gulley between each row, which must carry off all the strength of the manure deposited in the hill. If he will, on the first indications of the spot in tobacco, run his coulters deep and well, both ways, so as to break the ground thoroughly, disturbing the roots of the plant sufficiently to cause it to flop in the sun, he will, nine times out of ten, arrest it altogether, and greatly increase the product of the crop. This I never fail to do after the crop is nearly all topped, taking the heat of the day, and substituting a pair of light stretchers instead of the swingletree. I have been able effectually to divest myself of that troublesome insect the

cut-worm, by letting my hogs run in the tobacco lots for a week or ten days previous to the last ploughing, before bedding or hilling; it will be found effectual in all cases, for I speak from experience.

This being the first time I have taken pen in hand, I shall not touch on some other subjects relative to the tobacco crop until I see the fate of this, as I have no vanity to gratify—only a wish to be useful.

Yours, A Planter.

Nelson, *April* 7, 1843.

For the Louisville Journal and Dollar Farmer.

TO THE TOBACCO PLANTERS OF KENTUCKY AND INDIANA.

The undersigned having closely observed the tobacco market in the city of Louisville for the last two years, and feeling an interest in the success of that industrious and enterprising portion of our citizens, the tobacco planters, would beg leave to make to them a few suggestions, which may possibly be of some service, if it is only by attracting their attention to the subject.

There is a great amount of labor lost by half cultivating, half curing, rough handling, and general bad management of the tobacco crop, by a large portion of the planters. It is now pretty well ascertained that the crop of this year throughout the United States is much shorter than it has been for several years past: particularly in Virginia and Maryland, the crop is said to be short. The crop in Kentucky and Indiana, though something smaller than usual, is of better quality. As the tobacco market in Louisville is each year increasing and growing in importance, we may expect many of the dealers in the article in the east to come west to make their purchases. Planters may expect very fair prices, provided they will be more careful in handling and putting up their crops. As the crop is now housed, I will speak of the manner of putting it up for market. 1st. The entire crop should be divided into three qualities: the largest and finest leaves making the first quality; the shorter leaves, that are sound and clear of the ravages of worms, the second; and the ground leaves, or lugs and worm-eaten, the third quality. All of the first should be as near the same length as possible, and the same uniformity of length should characterize the second quality. If one portion of the crop is coarse, heavy leaf, and the other fine and light, they should be divided and put up accordingly, because the planter often loses much by mixing the cigar leaf with the heavy coarse leaf. There is often a great error committed both in the size and shape of the cask; also in pressing too hard. The casks are often too long, too small in the head, and with too large a bulge. When the bulge is too large, the hogshead will be very uneven and rough in appearance, when stripped for inspection and sale. When the hogshead is small in the head, and the leaf long, the sample cannot be drawn without breaking the ends of the leaves, which very much defaces and injures the appearance.

Much of the tobacco brought to this market is injured by hard pressing, to the amount of at least one dollar per hundred pounds, particularly that which comes from Green and Marion counties. The hogshead or cask should be four feet six inches in length, and three feet six inches in breadth

in the head, with a bulge only sufficient to hold the hoops well. Such a sized cask will contain, without too hard pressing, from thirteen to fourteen hundred pounds of net tobacco. The cask should not weigh more than one hundred and fifty or one hundred and sixty pounds, instead of two hundred pounds and upwards, as is often the case even when the tobacco is hauled from sixty to eighty miles, at an expense of fifty cents per hundred pounds for the unnecessary timber. Ash timber should be used when it can be had, because it is light and strong, and white and neat in appearance.

With a view to an improvement in the cultivation of the crop, we gave last spring, at the Louisville warehouse, premiums to the amount of one hundred dollars; and we expect to do the same next spring, with a slight alteration; and that is, to require each planter who offers a hogshead for premium to pay one or two dollars entrance money, which amount will be added to the amount of premium money. All the premiums except one were taken last spring by citizens of Hart county, Kentucky. Will it be the case again? What say you, planters of other counties, and of Indiana?

A great deal of our Kentucky tobacco is taken beyond the Alleghany mountains, manufactured into chewing tobacco, and brought back and sold in Kentucky as Virginia tobacco. All that is necessary to have a great abundance of it manufactured in our own State into a fine article, is, that the planters furnish our enterprising manufacturers with a good material, which they are entirely able to do.

ROBT. K. WHITE.

TOBACCO.

By a recent order of the Lords Commissioners of her Majesty's treasury, all leaf tobacco, in an unmanufactured state, may be imported from the United States of America into Great Britain and Ireland in packages of the same weight in which the same description of tobacco can be legally imported from the places of its growth. They have also authorized that the requisite alteration may be made in the law in the next customs amendment act, for to allow tobacco the produce of Mexico, America, South America, or the islands of St. Domingo and Cuba, to be imported into the United Kingdom, in bales containing eighty pounds weight each, from any place from which it may be legally imported for home use. Their lordships have also allowed tobacco the produce of Trinidad to be imported into the United Kingdom, in packages of the same size as those sanctioned for tobacco the produce of South America and St. Domingo.

From the Union.

TOBACCO IN GERMANY.

Letter from one of the heaviest tobacco dealers in Europe, to his friend, the late consul of the United States at Bremen:

BREMEN, *December* 26, 1845.

HONORED SIR: During your stay here, we several times had the pleasure of conversing with you, and furnishing some details about your tobac-

co trade. We therefore hope that it may not be called an intrusion upon your valuable time, if we address you a few lines to complete the statistics of this branch of our intercourse with the United States for the past year.

Imports here have been large, as might be expected from so abundant a crop as that of 1844–'45 proved to be. They reach—

	1844.	1843.	1842.
24,226 hhds. Maryland and Ohio, against -	16,978	18,483	20,106
1,571 do Virginia - - -	5,092	5,541	6,268
11,749 do Kentucky - - -	9,736	7,485	9,595
5,361 do stems - - - -	4,753	3,969	3,852
42,907	36,559	35,178	39,821

Sales have also increased considerably, and reach—

13,142 hhds. Maryland, against - -	11,917	10,481	12,234
2,544 do ground leaves - - -	1,250	1,501	1,079
2,229 do box - - - -	1,524	1,290	1,276
6,634 do Ohio - - - -	2,806	2,838	3,763
3,090 do Virginia - - -	4,202	4,360	5,473
10,570 do Kentucky - - -	9,569	6,481	9,127
4,106 do stems - - - -	5,563	3,447	5,087
42,315	36,831	30,398	38,039

And stocks at the end of the year in first hands, here, are—

5,922 hhds. Maryland and Ohio, against -	6,242	6,312	4,123
2,155 do Virginia - - -	3,666	2,738	1,557
3,340 do Kentucky - - -	2,229	2,022	1,018
1,330 do stems - - - -	209	969	447
12,747	12,346	12,041	7,145

The business during the last twelve months has had a more regular character than we have almost ever known it to have. The quality of the crop proved a desirable one, and better than any since 1840, particularly in point of *color*, which brought our dealers freely into the market; and as manufacturers also showed themselves anxious to secure stocks of this growth, all supplies found a ready sale at remunerating prices until the end of November, when the market became dull, various causes combining to render it so. Manufacturers had got into stocks; money became exceedingly scarce in Europe, in consequence of the mania to speculate in railroad stocks; which, however, has not extended to Bremen, where the horror to enter into anything like a paper speculation continues undiminished; and it was moreover put beyond a doubt that the grain crops in Europe, although we may not actually call them short, are far from being abundant, and will hardly suffice for the twelve months to come.

In August, reports of a short crop of tobacco, bearing the semblance of truth, reached our place from the United States, which caused quite a stir, and some lots of ordinary tobacco, probably about 2,000 hogsheads, were

taken by speculators; but, upon the whole, the business has been left to its legitimate course, and we again find it proved that nothing will go so far towards increasing sales as good qualities. Desirable tobacco is saleable even at this moment, whilst anything bordering upon ordinary cannot be sold even at ruinous rates. Your planters cannot devote too much attention to this fact, as nothing but their producing a better article than the inland (German) tobacco will increase the sale. We consider this of *much more* importance than a small reduction of the "Zoll-Verein" duty, which, for the consumer, amounts to but a very small item, whilst a better pipe of tobacco for the same money will so accustom him to the United States tobacco that manufacturers will be compelled to prefer it to the miserable stuff growing in our country. Since some years, a kind of reaty tobacco, grown in Mason county, has made its appearance, which promises to become a very important article in the manufacture of cigars. It is beginning to supersede Domingo tobacco. We saw 1,000 hogsheads sold this year at 8-22 groats. The average prices paid for tobacco are as follows:

					1844.	1843.	1842.
Maryland, from	$3\frac{3}{4}$ gts.	to $10\frac{1}{4}$ gts.,	average $6\frac{1}{16}$,	against	$5\frac{5}{8}$	$6\frac{1}{32}$	$6\frac{6}{16}$
G. leaf, from	$5\frac{1}{2}$	do $10\frac{3}{4}$	do $7\frac{1}{8}$	do	$7\frac{1}{24}$	$7\frac{1}{16}$	$8\frac{1}{4}$
Box, from	$5\frac{7}{8}$	do $20\frac{1}{2}$	do $9\frac{7}{8}$	do	12	$10\frac{5}{8}$	$12\frac{5}{6}$
Ohio, from	$4\frac{6}{8}$	do $15\frac{1}{4}$	do $7\frac{3}{4}$	do	$9\frac{3}{8}$	$8\frac{1}{8}$	$8\frac{1}{2}$
The prices of Virginia tobacco have been from					$2\frac{5}{8}$	to $8\frac{1}{2}$	av. $4\frac{1}{2}$
The prices of Kentucky and Mason county, from					$2\frac{3}{4}$	" 17	" 5

Another kind of tobacco has grown into importance this year, viz: Florida, which is extensively used in cigar making. It is a most abominable article as to taste or smell, but being splendid wrapper leaf for the eye, and much like Havana, it will take the field against the latter. It is imported in boxes, averaging 300 pounds, and we sold some ourselves at $1\frac{1}{4}$ rix dollars per pound. The common is not worth above 4.6. There were imported—

In 1843 - - - -	- 125 boxes, and nearly all sold.
1844 - - - -	- 200 boxes, and nearly all sold.
1845 - - - -	- 780 boxes, and nearly all sold.

It may be of interest to add some particulars about the other kinds of tobacco, which are brought to market in bales, averaging 120 pounds. The imports, which are about equal to the sale, were:

				1842.	1843.	1844.
6,490	bales	Havana	against	17,275	20,425	18,709
16,560	do	Domingo	do	9,762	10,145	7,123
21,990	do	Porto Rico	do	23,661	28,094	22,641
2,490	do	Varinas	do	8,192	9,025	10,993
6,560	do	Brazil	do	1,490	200	
4,950	do	Java	do			

Havana, Varinas, and Brazil cannot be driven out of the market by United States tobaccos, as they have a particular flavor, and cannot be dispensed with. Domingo finds a rival in Mason county and Florida; and Port Rico in Maryland. The growth of this island is an item, and would be a formidable rival but for two causes—firstly, the freight is too expensive, as it cannot be possibly brought here for less than $1\frac{1}{4}$ rix dollars per 100 pounds, whilst we regularly have Maryland at three quarters, and some-

times at three-eighths per cwt., and Kentucky at three-eighths and five-eighths; and, secondly, in consequence of the export duty in Porto Rico being another one-fourth. The cultivation in Porto Rico has much increased of late, and we bought several cargoes this year at 4 for prime, and 3 for second quality, &c. It appears planters find these rates remunerative. As we can pay them in linens and other manufactures, we almost give this trade the preference to that with your country, whenever we have a heavy cash balance against us.

As regards stocks of tobacco here, we find them larger than they have ever been, and should set them down in all hands at 50,000 to 60,000 hogsheads; of which about 20,000 hogsheads common are held by speculators, 12,747 hogsheads in first hands, and the balance held by dealers.

On the 29th of January the French government will enter into contracts for the supply of 300,000 kilograms of Kentucky tobacco, 200,000 kilograms of Maryland, 1,880,000 kilograms of Virginia, 1,400,000 kilograms of Kentucky, and 2,200,000 kilograms of Maryland. Tobacco, in this country, is a government monopoly, and these large quantities are required for sale.

From Wilmer and Smith's European Times, January 4, 1846.

LIVERPOOL ANNUAL TOBACCO REPORT.

The sales for the month amount to 1,137 hhds., of which 192 were Virginia leaf, 345 stemmed, 117 Kentucky leaf, and 483 stemmed. Of these, 155 Virginia leaf, 219 stemmed, 39 Kentucky leaf, and 48 stemmed, were taken for Ireland; 9 Virginia leaf and 53 stemmed, for Scotland; 1 Virginia and 33 Kentucky leaf for exportation; and the remainder, or 27 Virginia leaf, 73 stemmed, 45 Kentucky leaf, and 435 stemmed, by the trade. The imports 1,743 hhds.; the deliveries 1,066 hhds., of which 376 were for home use, 276 coastwise, 27 for exportation, and 387 for Ireland, and there now remain in the warehouse 1,596 Virginia leaf, 3,213 stemmed, 2,804 Kentucky leaf, 5,142 stemmed, 13 Marylands, 24 other sorts, and 4,530 hhds. unsampled, of which the greater proportion is stemmed.

The import of the year has been 13,370 hhds.; of which 1,426 were Virginia leaf, 2,509 stemmed, 1,037 Kentucky leaf, 3,855 stemmed, 13 Marylands, and 4,530 hhds. unsampled; of which 2,109 are from Virginia, 2,415 from New Orleans, and 6 from New York.

The deliveries of the year have been 12,341 hhds., viz.: 193 Virginia leaf, 288 stemmed, 332 Kentucky leaf, and 355 stemmed, to the trade; 234 Virginia leaf, 974 stemmed, 143 Kentucky leaf, and 1,159 stemmed, sent coastwise; 269 Virginia leaf, 51 stemmed, 1,700 Kentucky leaf, and 28 stemmed, for exportation; and 1,107 Virginia leaf, 1,529 stemmed, 478 Kentucky leaf, and 292 stemmed, to Ireland.

The sales of the year amount to 14,424 hhds., against 13,045 in 1844, and 12,739 in 1843. They consisted of 2,063 Virginia leaf, 3,003 stemmed, 2,902 Kentucky leaf, 6,435 stemmed, and 21 Marylands; of which 1,263 Virginia leaf, 1,864 stemmed, 598 Kentucky leaf, and 748 stemmed, (4,473 hhds.,) were taken for Ireland; 29 Virginia leaf, 485 stemmed, 3 Kentucky leaf, and 334 stemmed, (851,) for Scotland; 403 Virginia and 1,783 Kentucky leaf, with 13 Marylands, (2,199,) for exportation; 30 Virginia leaf, 133 stemmed, 67 Kentucky leaf, and 677 stemmed, (907,) for re-sale; and

338 Virginia leaf, 521 stemmed, 451 Kentucky leaf, 4,676 stemmed, and 8 Marylands, (5,994 hhds.,) by manufacturers; and there remain for sale 1,220 Virginia leaf, 2,627 stemmed, 2,170 Kentucky leaf, and 4,506 stemmed, to which will have to be added 4,530 hhds. yet to sample.

The weight of unmanufactured tobacco, upon which duty was paid in 1843, was 22,828,467 lbs.; in 1844, 24,250,010 lbs.; and this year, 25,852,199 lbs.—showing an increase over the previous one of 1,602,189 lbs.

As appears above, the sales of the month, though not large, have been fair, and the purchases confined principally for Ireland and the home trade; no speculation, and but little inquiry for export purposes.

About one-half of the new, now sampled, comprising an equal proportion of Virginia and western; the former proved, as expected, much better than the previous import; the latter good in every way, and both generally in fine order and condition.

In prices we make no alteration, the finer and most colory descriptions still commanding extreme rates; though, with ordinary and middling, holders are much easier than at the earlier part of the season; and unless some difference should arise between this country and America, (with a large stock, and manufacturers pretty well supplied, as is the case at present,) we cannot see any prospect of an improvement on the present quotations.

In London the stock is	27,300 hhds.	against	31,600	in 1844.
Ireland	2,350	"	2,000	"
Scotland	1,300	"	1,172	"
Bristol, Hull, and Newcastle	1,738	"	1,436	"
Here	17,302	"	16,273	"

Virginia.	Leaf.	Stemmed.
The import into this port for 1843, was	1,733	3,217
Do do 1844	1,446	3,381

Kentucky.	Leaf.	Stemmed.
Do. for 1843, was	6,085	2,687 and 10 Marylands.
Do. 1844	2,125	5,476 and 9 " and 4 other sorts.

The stocks on the continent not yet ascertained, but large.

JAMES BROWN, SON, & CO.

Liverpool, *December* 31, 1845.

APPENDIX No. 11.

COTTON.

For the Southern Cultivator.

ON THE CULTURE OF COTTON.

Mr. Camak: Having seen the report of Mr. R. P. Sasnett and others, who have been experimenting upon Dr. Cloud's plan of planting cotton, and having, in 1844, made a small trial myself, and discovering that my result approached so near in quantity that of Mr. R. P. Sasnett, I am encouraged to report, through your very useful periodical, the quantity of seed cotton which I grew per acre. The land, in a natural state, is a sandy ridge, had been cultivated several years, and was consequently somewhat exhausted; perhaps six or eight hundred pounds might have been grown upon it, unassisted by manure. In 1843 it was not cultivated, but was used as a pasture for calves. In February of last year I had the land broken deep with a scooter plough; after which, I hauled out my manure and laid it in piles at suitable distances. On the 2d of April I laid off the rows at the distance of two feet and a half the narrow way. This was performed with a very narrow plough. On the 3d of April the rows were run off the wide way, four feet, with a shovel plough, and the manure deposited in the check, in such quantity as to nearly fill the shovel-furrow at each hill; after which the bedding or ridging was performed the wide way with a very simple kind of turn plough, leaving enough of the middles unploughed to retain the small scooter marks as guides in planting. On the 4th of April the ridges were opened with a small scooter and light stock, the seed rubbed in leeched ashes, and a few dropped in each hill and covered with the feet. The ground being dry at this period, the seed did not vegetate till after the fall of a shower, which was 15th April. After the rain the middles were turned out. As soon as the cotton was up it was hoed, leaving three or four stalks in a hill. The second working was performed by running a small plough round the cotton, and leaving the middles unploughed, and hoeing out, leaving two stalks in each hill. In June the middles were ploughed, and the cotton hoed. At this period I discovered that the cotton was not inclined to branch properly; and, consequently, I thinned it down to one stalk in a hill.

At this time the plants were blooming, and on many stalks several bolls were found. Early in July I ploughed and hoed the ground very lightly; which finished the culture. On the 16th July I topped the cotton plants; it branched so as to fill up the row the wide way, and produce two thousand and thirty-four pounds per acre. Had the thinning been performed in proper time, I doubt not but that the product would have been larger. This fact is detailed as an error in the cultivation. One stalk in a hill is enough; and, if thinned as soon as possible, everybody knows that fruit will be produced the sooner.

The manure used was "compost," prepared from stables. The kin l of

seed planted was Rio Janeiro. I shall say something of this cotton in my next.

Yours,

MILES SCARBOROUGH.

MOUNT PLEASANT,
Meriwether county, April, 1845.

From the Washington "Union" of March 5, 1846.

COTTON MANUFACTURE.

We are permitted to copy the following interesting paper upon the cotton manufacture of Austria, from letters addressed to the Commissioner of Patents by Charles L. Fleischmann, esq., late of the Patent Office, now travelling in Europe. It is extracted from letters dated "Vienna, Austria, January 15, 1846."

Austrian cotton manufactures, &c.

The manufacture of cotton goods, although laboring under a great many disadvantages in regard to perfect machinery and a less experienced and skilful working class, has developed itself since the beginning of this century in one of the most important branches of Austrian industry.

In the year 1801 a Baron Kobliesky introduced into Austria the first English cotton spinning machines, and established the first cotton factories, which have since increased to 175, with 1,300,000 spindles. Some of these factories are now extensive; as, for instance, that at Pattendorf, which has 47,000, and that of Truman 32,000 spindles, producing yarn above the No. 100.

Within fifteen years the importation of raw cotton has increased five-fold, viz: in the year 1828, it amounted to 65,000 cwt.; in the year 1831, it was already double; in 1836, it reached 207,985; in 1837, 223,545; in 1840, 302,694; in 1841, 248,121; and in 1842, 321,377 cwt.

In the year 1834 the government reduced the import duty from 3 florins 30 kreutzers to 1 florin 40 kreutzers per cwt., in order to encourage this important branch.

The above-stated numbers of spindles produce yearly 214,896 cwt. of yarn and thread of the following numbers: from 1 to 30, 12,613,074; of 32 to 60, 8,313,327; of 62 to 100, 283,398; above 100, 17,410, and thread, 262,410; in all, 21,489,619.

In the early stage of the development of this branch of industry, the importation of yarn to No. 50 was entirely prohibited, but afterwards admitted under a duty from 30 to 81 florins, according to the degree of fineness of the article; in the year 1833 it was reduced to 20 florins; and in March, 1845, to 10 florins, or about $5 per cwt.

This reduced duty increased the importation of fine yarns, in which Austria cannot compete with England. In 1831, it was only 6,773; in 1833, 10,670; in 1838, 57,766; and in 1842, 61,411 cwt.

Austria imports three different kinds of cotton—the Macedonian, Egyp-

tian, and American. The Macedonian is used for the most common yarn, or the numbers from 1 to 10; the American for the numbers from 12 to 30; for the fine numbers from 32 to 60, partly American and partly Egyptian; and for the numbers above 60, the best Egyptian.

The average price of the different kinds of cotton stood, in 1841—Macedonian, 32 florins; Egyptian, 48 florins; and American, 37½ florins, per cwt.

The price of Egyptian or Maco cotton has, since 1841, diminished in price, and in 1844 it could be bought for 27 florins per cwt.; the middle quality of American fell in the same period from 37½ florins to 25 florins per cwt.

The Egyptian cotton is of great importance to Austria. In the first place, it is of superior quality, and can be used for the finest numbers; and, secondly, it employs its vessels in commerce with Egypt for the transportation.

The whole amount of imported cotton can be estimated at one-eighth Macedonian, two eighths Egyptian, and five-eighths American—computed at a value of 9,860,000 florins.

When to this sum for raw cotton the expense of manufacturing into yarn is added—amounting to 214,896 cwt., valued at 5,260,000 florins—the value of yarn produced in the Austrian manufactories amounts to 15,120,000 florins.

The low rate of labor has prevented the general introduction of power-looms. Most of the yarn is woven into different goods by hand; and, according to the official statements, there are turned out 5,800,000 pieces, at a value of 20,760,000 florins.

Great as the increase of manufactured cotton goods appears within twenty years, there is yet room for a far greater extension. The yearly consumption of cotton goods amounts to 218,000 cwt., of a population of 36,000,000, or two-thirds of a pound or six yards per head; which is considerably less, when compared with the countries of the German league, where it amounts to two pounds per head.

The extensive production of English cotton yarn stands to that of Austria as 1 to 12; to that of France as 1 to 4; and to those of the German league as 4 to 3. The importation of cotton yarn into Austria, which amounts to 47,337 cwt., was in the German league three times greater; in France, very small.

From the Union.

COTTON IN INDIA.

New York, *September* 22, 1845.

The Zenobia, which arrived at this port on Saturday morning last from Calcutta, East Indies, brought home one of the American cotton planters, who, some five years since, entered the service of the honorable East India Company as a superintendent of cotton farms in their extensive experiment, made to grow American cotton in that region, and to improve the cultivation of native cotton. I have had much conversation with Mr. T., who went from Mississippi; and after having served the government for five years, the term of his engagement, has returned, as stated, in the Zenobia. He has communicated to me much valuable and interesting information in relation to India.

He estimates that the experiment has cost the government about $500,000, and that it has resulted in the most complete and signal failure.

In 1840 an agent of the government came to the United States, and repaired to Louisiana and Mississippi, where the growing of cotton has been carried to the greatest state of perfection, and where he engaged ten Americans who had been employed in superintending cotton estates in that section of the Union for several years. They were well recommended by the most respectable planters. They left with the agent for India, via England, and took with them large quantities of the best American cotton seed, agricultural implements, cotton-gins, presses, &c.

The planters were engaged at an average salary of about £300 each, with an allowance for subsistence of £100 more. Each entered into a contract to remain in the service of the company five years, and to conduct the experiments in such parts of India as the government should point out. Of the ten persons thus engaged, three, after the first year, returned home, being paid their salaries up to the time of leaving, but were left to bear their own expenses home; while, according to the agreement, those who remained five years were to have all their expenses borne from America to India, and from thence, at the expiration of the service, back to the United States. Seven of the party remained to the end of their engagement; one of whom is Mr. T., who has just arrived in the Zenobia.

He says, on reaching India their party were distributed to different parts of the Indian empire, in order that the experiment might be tested in reference to the different soils and varieties of climate in that vast empire.

One (Mr. T.) was placed at Calpee, in the district of Bundelcund. Another was stationed at Goruckpore, under the Napal hills; another in Dooab; another was located in Soomapore; another at Humeapore, in the province of Banda; another at Raatch, in Bundelpore; others in Coimbatore and at Surat, on the western side of the peninsula.

After experimenting a year or two at each place without a prospect of success, they were changed to other localities, so as to give every district in India, as far as possible, a trial. Mr. T. was changed from Bundelcund to Rungpore, North India, near the base and in full view of the Himalaya mountains, which were covered with perpetual snow. Others were changed to Dahwar, in the southern Mahratta country.

The American planter placed at Raatch, during a rebellion which commenced with the Decoyts, (robbers) had his premises attacked, his houses sacked and burnt, barely escaping with his life and the clothes he wore.

In every part of India where the Americans tried the cultivation of cotton, and endeavored to instruct the natives in the best mode of culture, they most signally failed. Those who remained used every exertion to succeed, as they were liberally paid, having every facility granted that they could ask, with the expectation of being handsomely rewarded if they succeeded.

Mr. T. thinks the two great and insuperable difficulties in the way of cultivating cotton in India are attributable to the two great extremes of *dry* and *wet weather*, either of which is peculiarly fatal to cotton. During the continuance of the rainy season, the cotton plants grow with unwonted luxuriance and rapidity, to be as suddenly checked and cut off by the intense heat of the sun which pours upon them during the succeeding season. When the dry weather sets in, the sun ripens the bolls prematurely, when apparently not more than half grown, while the leaves of the plant are crisped and burnt to a brown color by the intensity of the solar heat.

In lower Bengal the rainy season commences late in May, and continues till October. In central India the rainy season begins about the middle of July and lasts till from the 1st to the 15th of September.

In lower Bengal as much as 76 inches of rain usually falls in 12 months. In central India no crops can be anticipated with much less than 13 inches of rain. Eleven inches never fails to result in a famine, which is dreadful in its effects upon the natives.

In addition to the unconquerable difficulties of the climate, the cotton plant is exposed to the fatal attacks of destructive insects. There is one which lays an egg in the flower of the plant. Before the boll matures, the worm forms within it, which feeds upon the green and tender fibres of the cotton, eating out all the cotton within the boll before it matures, leaving only a lock or two in some bolls, or pods, while in others not a fibre is left. In some parts of India it is also subject to the attacks of white ants, which cut down the plants while young, or attack the young pods and cut them off.

All that the Americans could do with their best exertion only enabled them to raise, on the average, about ten pounds of clean cotton to the acre from the best American cotton-seed, and only seventy pounds of clean cotton to the acre from native India cotton-seed.

Mr. T., before leaving Mississippi to go to India, superintended a cotton estate near Rodney, in that State, in 1839, on which he raised over nine hundred pounds of clean cotton to the acre. He says that year he made a fine crop, actually sending to market two hundred bales of good cotton, averaging four hundred and fifty pounds each, from ninety-six acres of land. What a contrast this to cropping in India!

Mr. E., one of the American cotton growers who went to India, and was stationed at Goruckpore, put two hundred acres in cotton, from which he gathered only two hundred pounds of clean cotton. The most those sent to Coimbatore could do was to raise, in a favorable year, two hundred pounds of seed cotton to the acre—equal to about fifty pounds of clean cotton. The most Mr. T. could do was to raise, the first year, ten pounds of clean cotton from American cotton-seed of the Mexican variety, (the best) and seventy pounds of native cotton, to the acre. He says the American seed carried out from about Rodney (the best in America) deteriorated every year; the staple or fibre growing shorter, while the yield grew less. It is his firm conviction that if the American seed be planted over and over again in the same soil, in India, in *five years* it will totally cease to mature any cotton whatever. He also says, by changing it to other districts, it may be made to yield something a few years longer, but would ultimately run out.

From the Southern Cultivator, July 4.

AMERICAN COTTON IN INDIA.

It appears, from a report of the Bombay Chamber of Commerce, that the experiments in growing American cotton in India have not been entirely unsuccessful, particularly in the neighborhood of Hyderabad, under the superintendence of Captain Meadows Taylor. The following is an extract from the report of the committee of the Bombay Chamber:

" Your committee place in the appendix to the present report the letters of Captain Taylor relative to the samples, which give a very favorable

account of the progress making in the culture of New Orleans, Sea island, and Bourbon cottons. It is gratifying to perceive that the native growers are engaging actively in the cultivation of these varieties, and that instead of being with difficulty persuaded to make the smallest experiment—as has too often been the case before in other localities—they evince the greatest eagerness to obtain seed for sowing. The crops of Bourbon and Sea island on the bank of the Krishna are described as most luxuriant, and the success of the New Orleans appears to be beyond a doubt. Captain Taylor states that he has given directions for the whole of the cotton grown from the seed furnished to be collected and sent to Sholapore; and he adds that he purposes afterwards forwarding it to Bombay, in order to ascertain its value in our market. Your committee trust that the time is drawing nigh when we shall be able to calculate on a regular supply of such cotton. There can be no doubt that it would fetch a good price here for shipment to the home markets, and that it would amply remunerate both grower and dealer."

From the Gardeners' Chronicle, August 30, 1845.

CULTIVATION OF COTTON IN INDIA.

In resuming the subject of the cultivation of cotton in India, I must request your attention to an error which has crept into my communication. I had stated that the American species—that is, gossypium peruvianum and G. barbadense—though long introduced into India, still retain their distinctive characters. I then mentioned some corroborative facts, and concluded by stating that these facts show "persistence" of character, even in the midst of the Indian species. Your printers have made me say "perverseness" of character, which is a manifest contradiction to what was before said. I am glad, however, of recalling attention to this part of the subject, hoping that some of your correspondents may say something respecting the influence of different species of the same genus in hybridizing each other when grown in large quantities in the same open country. I have said on each other, because if the Indian species, from their vicinity, deteriorate the American species, these, on the contrary, ought to have some influence in improving the species indigenous to India. Some, indeed, are disposed to look with hope in this direction. Dr. Burn, indeed, in the very last letter, dated in May, which I received from him, says: "I am full of hope that something good may be obtained by crossing the foreign with our native cottons." In the mean time, however, he has made an experiment in crossing the two Indian species with each other. Of these, G. arboreum, as its name indicates, grows to a tree—bears comparatively little cotton; but this little is of a fine silky nature, and comparatively long in staple: the other species, G. herbaceum, which ought rather to be called G. indicum, as it will grow into a shrub, though only herbaceous in the south of Europe, is the source of the different cultivated varieties of cotton in different parts of India, some of which are of very excellent quality, as I hope afterwards to show. I give the results of Dr. Burn's experiment in his own words, which were communicated in a letter to Col. Sykes, and which has been lithographed at the India House, and of which I send you a copy, with colored drawings of the plants:

"The plant from which this is a specimen was sown at the beginning of the monsoon, in July, 1844, along with other plants of the G. arboreum. It grew up and ripened its produce; but it differed from them in habit considerably. They grow and blossom all the season, from November, until checked by the heat in April. It blossomed and yielded all its produce in the space of two months, as the G. h. does, and it was free from the chief fault of the G. a., viz: that of yielding too small a quantity of produce. In short, it had all, or nearly all, the good qualities of the parent plants. The plant grew to the height of six feet, and the lower lateral branches, four in number, were two feet in length each; the remaining ones being shorter gradually up to the top of the plant. The number of blossoms was 60; but only about 50 remained to yield produce; the others falling off. The color of the stem and other parts was greener, like the G. h., and not so black or dark colored as the G. a. The whole plant was also more hairy than the G. a., and resembled in this respect G. h., the most hirsute of all the varieties of the genus gossypium. The color of the blossoms was chiefly red, but at the roots of the petals the yellow color of the G. h. flowers was vivid, and more distinct than is shown by the dried specimen. The produce from the 50 bolls weighed equal to four rupees and three-quarters, or 855 troy grains; and for the sake of comparison in results, an equal weight of produce from G. a. was examined at the time along with that of the cross plant. The results were as follows:

Cross-plant wool, grains - - - -	$239 =$	28	per cent.
seed, grains - - - -	$607\frac{1}{2} =$	71	"
loss and dust, grains - - -	$8\frac{1}{2} =$	1	"
	855	100	
G. arboreum wool, grains, - - -	$191\frac{1}{4} =$	$22\frac{1}{4}$	per cent.
seed, grains - - - -	$658 =$	77	"
loss and dirt, grains - -	$5\frac{3}{4} =$	$0\frac{3}{4}$	"
	855	100	

"This shows clearly that improvement as to quantity of wool has been one result of the crossing. 28 per cent. is, I believe, equal to the yield of the best New Orleans produce in America; and, in this instance, the quality of the wool, in my opinion, is quite equal to the best* New Orleans to be found in the English markets. It is superior to the best Broach or "Surats." One fact, however, should be noticed—the yield of the G. h. here, on fallow land, is commonly 33 per cent. The G. a. and G. h. are eminently suited to the climate here, which none of the foreign varieties are. A knowledge of the climate, as to distribution of moisture, is the grand desideratum in India for successful cotton culture. The average fall of rain at Broach, for 1843 and 1844, was 38 inches—$31\frac{3}{4}$ per cent. The average of Bombay, as given, I believe, by Mr. Noton, is $76\frac{1}{2}$ inches; showing an excess over Broach of $38.18\frac{1}{4}$, or double in amount. Now, the two last seasons at Broach are considered to be above the average fall, and too much for successful cotton crops. Cotton cannot be raised near Bombay; and if at

* A sample parcel is sent along with this by same post.

Broach the fall of rain was any thing like that at Bombay, it is clear no cotton bushes could grow; they would be rotted by the excess of moisture, as they have been in all low places during the past two seasons. These latter remarks apply chiefly to G. h. and G. a., for each variety of cotton plant varies much in habit. Crossing appears to me to be a very likely mode of obtaining a better and more productive kind of plant than is at present cultivated in India. Witness the varieties of the potato thus acquired; of the Hopetoun oat, now so universally esteemed in the Lothians. Use the pollen of some of the fine foreign cottons to impregnate the blossoms of the hardy, and suited to climate, (G. a.,) and is it too much to expect to permanently improve upon it? In the case now under notice, I am perfectly satisfied of the success so far; but will the produce from the seed of any plant retain the improvement? We must try and see the results next season. If an acre of land were planted with 7,000 plants—not too many—and they yielded at the rate above stated, or take it only at grains, 720 each plant, then the wool would amount to 201 lbs.; and at 4*d.* per lb., or 6 lbs. per rupee, its value would be 34 rupees, a sum one-third of which would be ample to cover the expenses of cultivation, if judiciously gone about.

"The number of seeds from 855 grains of produce was—

Cross-plant	- 676 good.	G. a.	762 good.	Difference in number, 62.
	27 bad.		3 bad.	
	703		765	

"A. BURN.

"Broach, *January* 25, 1845.

"P. S.—It is clear the cause of the partial success attending the experiments in cultivation of the American cotton plant, both at Coimbatore and Dahwar, depends on the moisture of both monsoons affecting the atmosphere of those two places, on different sides of the Gats, with a degree of moisture, the continuance of which is sufficient to admit of the growth and maturation of the produce. The pass in the Gats at P. admits of this.

"A. B."

I sent Colonel Sykes a specimen of a hybrid cotton plant, raised here. I am full of hope that something good may be obtained by crossing the foreign with our native cottons. What think you?

Dr. Burn, commenting on this result, says: "Crossing appears to me to be a very likely mode of obtaining a better and more productive kind of plant than is at present cultivated in India. In the case now under notice, I am perfectly satisfied of the success so far; but will the produce from the seed of any plant retain the improvement?" I must conclude with asking, what do you, and what do your correspondents say to the course of experiment, and to its probable results?

J. F. R.

GROWTH OF COTTON IN INDIA.

Three years ago I addressed the subjoined letter to a gentleman in Liverpool, connected with the trade to South America, and he forwarded a

copy of it to his partners in Peru, who did me the honor to translate it into Spanish, and circulate it among the planters there; but with what effect, I know not. Now, it seems to me to be quite as applicable to India as Peru; and it every year becomes more evident how vitally important it is for us to endeavor to grow that indispensable article, cotton, in our own colonies, rather than continue dependant on the United States for our supplies; as a war of two years' duration, or even a serious outbreak among the negroes, (which is very likely to occur if we have a war with the States,) might set fast all our mills, and deprive our work-people of bread.

I am aware that many experiments, having for their object the growth of a better quality of cotton, have failed; indeed, so long ago as the year 1828, I sent seed of many varieties to Calcutta, where they were put into the hands of the Horticultural Society; but I heard no more of them, and it did not then occur to me that the failure of all attempts to grow good cotton would be probable, from the overwhelming preponderance of the native cotton, planted in the same vicinity. The growing of better kinds of cotton may have been attempted in India, with the precautions suggested to the Peruvians; but if it has, I have never heard of it; and I am convinced if success is to be obtained at all, it must be sought for in that direction.

T. G.

The following is the letter above alluded to:

"I have for some time intended to call your attention to the importance of attempting to grow fine cotton in Peru. We have been, as you are aware, consumers of Peruvian cotton to some extent for the last six or eight months, and, from the observations I have made on it during that time, I have no hesitation in saying that it possesses many excellencies. It is long enough, (almost too long,) very sound in staple, and, when well managed, of a very good color; its defects are coarseness and harshness of staple; and if these could be removed, I do not see what is to prevent its rivalling the Egyptian and Sea island cottons, any considerable approximation to which would very materially enhance its value; seeing that the highest quotation for Sea islands was last week 30*d.*, whilst the highest for Peruvian was no more than 6½*d.* With the view of improving the quality of cotton in Peru, I would strongly recommend you to send seeds of various kinds, packed in air-tight boxes, particularly Sea island and Egyptian, which some of the cotton brokers would easily procure from the spinners using these descriptions; and, judging from what I hear of the climate of both countries, I should think the Egyptian would go to a very similar atmosphere and mode of cultivation to that where it has been raised, which would be very likely to render it much more easily acclimated, and of course make it much more likely to succeed than a sort of cotton which had been grown under dissimilar circumstances of soil, climate, and mode of cultivation.

"These seeds, when sown, ought (with the exceptions hereafter to be mentioned) to be planted at such a distance from all other cottons as to render it very unlikely for the wind or insects to carry the pollen from the flowers of one kind to those of another; for, without this precaution, such is the tendency in many genera of plants to hybridize or cross breed with each other, (and I believe, from what I have heard, that there is this tendency in the different varieties of cotton,) that, however good the quality in the first instance, they would all revert to the old variety in a season or two, in consequence of the great preponderance of that variety over any

newly introduced ones. So much are the growers of turnip seed, for sale in England, aware of the importance of attending to this, that the greatest precautions are taken to remove all cruciform plants from the vicinity of the field, whilst their turnips are in flower, as there is such a tendency in them all to hybridize that the quality of the seed is often injured by the wild mustard (*sinapis arvensis*) springing up in the same or adjoining fields; whilst by carefully selecting, on the other hand, the best bulbs for seed, and by judiciously crossing one variety with another, new sorts are obtained, combining the excellencies of both. This leads me to observe, that probably seed of foreign varieties of cotton may not thrive well in the first instance; and I would therefore very strongly recommend the gentleman who makes the experiment carefully to select seed from the plants on his estate which he sees are producing the best and finest cotton, and sow them in contact with a few seeds of each of the sorts you may send out to him, carefully removing them in every instance, as far as is practicable, from the vicinity of all other cotton; and then again sowing the seed which is obtained from these experiments, and carefully examining the cotton growing upon each of them. It is more than probable that some of the plants will be varieties partaking of the character of both the parent kinds; and by selecting the best of these, and sowing them alone, (still at a distance from all other cotton,) there is but little doubt that much benefit will be derived by the persevering and skilful cultivator. I have heard it stated that the origin of the Sea island cotton is to be traced to something of the kind. An observing and experimental planter, by carefully examining his plants, and sowing seed always from those alone which produced the largest and finest cotton, at last arrived at that excellent quality known by that name. Look again at what has been done in Egypt, by the introduction of seeds of better cotton; and there this improved variety has by no means had a fair chance of showing what it is capable of becoming, inasmuch as the wretched cultivator has not the slightest inducement to improve its quality. He gets no more per pound for the finest and cleanest cotton than he does for the coarsest and dirtiest, and therefore it is not very likely to improve under his care. But with all this neglect and want of management, we can see, by what it is, what it would most probably become in the hands of an enterprising and skilful man, who knew that every improvement he made in its quality would be to his own advantage. Assuming that our Peruvian friends would so far improve the quality of their cottons as to double its value in this market, (and I do not think myself too sanguine in expecting even more than this,) with very little extra labor, nearly all the additional price would be profit.

"But supposing that even cross-fertilizing, or hybridizing, as the horticulturists call it, does not frequently naturally occur in cotton plants, we all know that it is very easy to effect it artificially, by prematurely unfolding the petals, and with fine scissors cutting away all the stamens before impregnation takes place. This requires to be carefully done, so as not to injure the petals, and they will then close again of themselves; and when they expand naturally, then impregnate the stigma of the flower with the pollen of the kind you want to cross with. We owe many of our finest varieties of fruits to this practice. The late Mr. Andrew Knight, in particular, was very successful in raising new kinds in this way. And it appears to me, from the experiment I have made, that the more frequently this cross breeding takes place, the more easy (within certain limits) it is

to extend it, until cultivation has so completely changed the character of the plant that it bears very little resemblance to its original stock. There is nothing growing wild like our cabbages, turnips, and cauliflowers, nor even like our carrots, celery, and asparagus. Where are the originals of our wheat, barley, rye, beans, and peas? Many of these appear to be so completely transformed by cultivation, that we do not know where to look for the original stocks from which they have sprung.

"THOMAS GARNETT."

From the Southwestern Farmer.

MR. HAMMOND'S REPORT.

We give, at the conclusion of this notice, the report of a committee of which our friend, J. H. Hammond, was chairman. We congratulate him on the knowledge of farming that he displays. We see how readily the educated and intelligent can learn the business of farming. But a short time since, our old school-mate was up to his eyes in politics: he now retires to the field, there to live a quiet, peaceable life. We rejoice at it, and can but repeat the remark we made to him before he was elected governor: "You are wrong—you have no business in that sphere—seek your ease and peace —it suits you better, and will give you satisfaction." His answer was then, as his works answer now: "I will do so as early as the force of circumstances will permit;" or to this purport were both.

We again congratulate him, and also our country, in the success of our friend. We also press on all agriculturists any articles from the pen of Hammond; he will, we feel assured, give all matters that he writes on his minute and particular attention. We have known him from both of our boyhoods, and know him to be talented and observing; and, more than all, when he does apply himself, it is an application deserving and insuring success.

As we are his senior in planting the cotton, especially in personal attention to it, we beg to give him a hint or two. We may err in our notions; and why we say so, is, that we differ so materially from so large a number of farmers. We think that very early planting is disadvantageous. And to define early planting: We think the last week in March is early enough at any time, even for this year, when it will be borne in mind the fruit trees were quite green at that time; to plant as early as the 15th or 20th of March is "very early." We generally judge it to be time to plant corn when the "leaf of the oak is as large as the squirrel's ear;" many of our planters have planted cotton as early. We think cotton planted from the 1st to the 10th of April is early enough for old land, and have known, by several crops, that the later planting—say the 10th—was considerably better than the early; we know this not only by our own weights and measures, but also by others.

We would make an exception to early planting. New ground and rich fresh land has such a tendency to make weed, that it is necessary to plant as early as a stand can be had—so all think; we would not object, but think that judicious culture would make a different result. We would act precisely as with the tree that produced wood instead of fruit—amputate the roots. We think that if the land has been broken up very early, and

left to be consolidated by rains, then planted about the 5th to the 10th of April, thinned out as early as it was up, cultivated deep and late, the stalks would set the fruit and ripen in time. Do we not thus with fruit trees, Irish potato, and sweet potato—the latter, too, by either cutting off tops, or feeding with calves? And why not a similar practice with the cotton plant?

The cotton plant is a very tender plant if treated as it was some ten or fifteen years since—some three to six bushels of seed sown per acre, and it not thinned out until third leaf had appeared. It has been raised in a hot-bed, and no wonder it be tender; but if sown thinly, and then thinned out to single stalks, we think it a hardy plant. There is no use in trying the hardihood of the plant—it is unlike corn. It has a tap root, grows in dry weather, and unless the land has not been properly prepared, or remarkably dry, it will improve by hot or dry weather; but corn having superficial roots, should be planted early as possible, that it may ripen before the drought sets in. If cotton will make 1,000 pounds per acre when planted late in May, there can be no fears to plant 10th April. The farmer can place his land in excellent order—have his corn cleaned handsomely; and when cotton is up, he can push it to the utmost. We request our friend H. to plant one acre of cotton, even now, after his seeing this, on a piece of well ploughed land, in the same field that he has now even scraped over. Just open out furrows where the cotton now stands, which will destroy the cotton that has been scraped. Our impression is, that the difference will be very slight, and, if adopted generally, would give considerable time to manure, plough, and improve, instead of giving cotton the additional working necessary. The land that we have known planted late would not, average seasons, make any thing like one-third more by early planting; and if the extra labor was applied to improving it, we doubt if it would yield as much. Understand, we do not advocate either late or early planting—that is, after the 25th of April or before the 1st; and only wish to show there is not so vast difference between planting 1st April and 1st May. What would be the gain to any farm by this extra month's work? P.

—

REPORT OF THE COMMITTEE OF THE BARNWELL AGRICULTURAL SOCIETY ON THE CULTURE OF COTTON.

The ground cannot be too well prepared for cotton.—If it has rested one year it should be broken flush, as early in the previous fall as possible, and headed just before planting. If it has rested two years or been planted the preceding year, let it be listed as early as it can be done, and two furrows thrown upon the list. Immediately upon planting, let two more furrows be thrown up, and the balk broken out completely. The common method of running three furrows, and planting on it, throws the winter's portion of the crop work upon the laborer during crop time, and is inexcusable, unless heavy clearings are absolutely required. The reason for not listing after one year's rest is, that the vegetation matter will be too abundant, and too coarse to form a substratum to receive the tap-root.

Cotton should be planted early.—It may increase the difficulty of getting a stand, and give the plant, for a long time, a puny appearance, but every stalk of cotton planted in March, or first week in April, that survives, may

be readily distinguished in any field that has been replanted later. It bears more, and earlier, and stands all the vicissitudes of June, July, and August better. There are several methods of planting. Your committee recommend planting in spots regularly measured by the dibble. It is somewhat tedious, though less so than is generally supposed, and certainly does not take as much time as both to drill and chop out; nor is time so valuable at that period as when the latter operation is required, while a better and more regular stand may be secured. There is no land, or but little, in our district, in which cotton rows should be over three feet apart, or the cotton further than fourteen inches in the drill, one plant in a place. To make a large crop there must be an abundant supply of stalks. When the weather is too wet to plant, time may be often saved by dropping the seed, but not covering until the ground is drier. If, however, it cannot be covered in three or four days, it is time lost, for it must be replanted. Always cover lightly, under any circumstances; and always plant on something of a bed, in any land. It keeps cotton drier, and affords more air when it is young; it enables you to get at it in working. By increasing the surface, it absorbs more moisture if it is too dry, and gives out more if it is too wet; and, in both cases, gives you the advantage of a vertical sun on the tap-root, which hastens the maturity of the bolls—a vast desideratum in our climate. On this account the bed can hardly be drawn too high at the list hoeing in any season.

In cultivating cotton, whether with the plough or hoe, the chief object is to keep down the grass, which is its greatest antagonist, bringing all, or almost all other evils in its train. It is not so essential, in the opinion of your committee, to keep the ground stirred, as is generally supposed, and by no means requisite to stir it deep—at all events not to our light soil. If it be well prepared, deep ploughing is not only unnecessary for any of our crops, but often highly injurious to them, while it rapidly exhausts the land by turning it up fresh under a burning sun. Much unnecessary pains is usually taken and time lost to work the plant in a particular way, under the supposition that it is a peculiarly delicate one. If it survives its infancy, few plants are hardier. It is often found to reach maturity in the alleys, where the mules walk with the ploughs following, and the laborer tramps backwards and forwards. Sometimes it will bear fruit in turnrows used frequently for wagons, while it really seems to derive benefit from being bitten down almost to the ground by the animals; it will bear almost any usage better than it will that mortal enemy, grass.

The most critical operation in working cotton is *thinning*. It should be done with great care, and, if early, with the hand. In a dry year, it cannot be done too early after the plant is up. In a wet one, it may be profitably delayed until it has begun to form, or later even. On the experience, observation, and judgment of the planter, in this matter, every thing depends, as each year brings its own rules with it. Where circumstances are favorable, early thinning is of course the best. Some planters always top their cotton; others never do. Your committee are of opinion that it seldom or never does harm to do so; but whether it is worth the trouble is a doubtful question. Those who have no clearing, or other important employ for their hands, would lose nothing by devoting three or four days to this operation early in August. Those pressed for time might gain by omitting it.

Too much pains cannot be taken in preparing cotton for market, for they

are all well remunerated by the additional price. The first thing to be attended to is to have it gathered free of trash. With a little care, wonders can be effected in this way, and hands with a short training will pick almost if not quite as much without trash as with it. It should never be gathered when wet. And here it may not be out of place to remark, that one of the very best sanitary rules of a plantation is, never before frost to send out your hands to pick until the dew has nearly or quite disappeared. It saves time in the long run, as well as health and life. Cotton should never be ginned until the seed are so dry as to crack between the teeth. If damp, it is preferable to dry it in the shade, as the sun extracts the oil and injures the staple. If by accident, however, it gets wet, there is no alternative but to put it on the scaffold. It is of great importance to sort the cotton carefully into several qualities, in ginning and packing; for by mixing all qualities together, the average of the price is certainly lowered. A few old hands, or very young ones, breeding women, sucklers, and invalids, will earn excellent wages in a gin-house at this occupation. Neat packing is of no small importance in the sale of cotton, and no little taste may be displayed in making the packages. The advantage of square bags is universally known, and the committee are astonished that any other should ever be made now.

Every kind of manure is valuable for cotton.—Every kind of compost, green crops turned in, cotton-seed, and even naked leaves, listed and left to rot, improve this crop. When planted on cotton-seed, and sometimes on strong stable manure, it is more difficult to retain a stand, owing probably to the over-stimulus of these strong manures. So on leaves, unless well rotted, the cotton will long continue to die, in consequence of the leaves decaying away and exposing the root too much to sun and rain. These difficulties may be avoided by a little pains, and by no means justify the opinion entertained by some, that cotton should never be planted on freshly manured land. The only question is, the cost of the manure. A great deal may be made on every plantation, without much trouble or expense, by keeping the stables and stable-yard, hog and cow pens, well supplied with leaves and straw, and also from pens of corn cobs, sweepings from negro and fowl-house yards, and rank weeds that spring up about them, collected together and left to rot. Whenever the business is carried further, and a regular force is detached to make manure, at all seasons, and entirely left out from the crop, it becomes the owner to enter into a close calculation of the cost and profits. In many agricultural operations, such a course the experience of all countries has proved to be profitable, but these operations partake rather more of the farming and gardening than planting character, and whether the same method will do for the extensive planting of short staple cotton, remains, in the opinion of your committee, yet to be tested. If any thing like an average of past prices can be maintained, it is certain that more can be made by planting largely than by making manure as a crop. If, however, prices continue to fall, and the growing of cotton be confined to a few rich spots—those susceptible of high manuring—then our whole system must be changed, our crops must be curtailed, and staple—labor losing its past value—the comparative profit of a cotton and manure crop, will preponderate in favor of the latter. As a substitute for manuring on a large scale, resting and rotation of crops is resorted to. In our right level land, the practice of resting cannot be too highly recommended, and, by a judicious course—such as resting two and planting two, or at most three

years—our lands may not only be kept up forever, but absolutely improved. From rotation of crops but little is gained for cotton. After small grain, whether from the exhausting nature of that crop on light lands, or because the stubble keeps the ground always rough and porous, cotton will not do well. After corn it is difficult to tend, as, from our usual manner of cultivating corn, grass is always left in full possession of the field. It does best after cotton, or after a year's rest. Rest is the grand restorer, and the rotation chiefly required in the cultivation of cotton.

J. H. HAMMOND, *Chairman*.

From the Nashville Agriculturist.

PREPARING FINE COTTONS FOR MARKET.

EUFAULA, BARBOUR COUNTY, ALABAMA,
April 25, 1845.

GENTLEMEN: Yours of the 14th instant was received by last night's mail, calling on me for my system of preparing for market fine cottons. As it at all times affords me the greatest pleasure to do or say any thing that may in any way be of any service to my brother farmers, I lose no time in replying to your inquiries.

But to the point. I live in latitude about 31½. The land I cultivate is poor pine land, which would not sell at the present time for five dollars per acre, (though I am at this time making a great effort to enrich it by manuring) We cultivate our cotton on the usual plan adopted in this section of country, taking care to keep it clean, and not suffering it to be injured by grass or weeds—ploughing it late with the sweep or buzzard plough; so that when we commence picking in the fall, there is not a particle of grass or weeds. We commence picking out as soon as the cotton opens; and here is one of the great secrets of making fine cottons. Last year we commenced on the 7th of August, and picked out in that month nearly one-third of our crop, as we made but about one hundred thousand pounds of seed cotton. I find at page 132 of my Farming Memorandum, for 1844, the following entry, to wit:

Picked out in	August	21,000	pounds.
Do.	September	36,000	"
Do.	October	38,000	"
		95,000	

So you discover that our crop was nearly out by the first of November. We take all the care we possibly can in picking it out of the field, not suffering our pickers to pick any; or, at any rate, we avoid trash as much as possible, as we average only about 100 pounds per day; and it is not uncommon in this country to nearly double that amount in picking. It is then dried on a scaffold. We always require our hands to pick it over as the baskets are emptied on the scaffold. It is only the hands that are not employed in weighing that are engaged in picking it over. After it is dried we pack it away closely, and suffer it to remain in bulk some three months, for the purpose of drawing oil from the seed, which gives the cot-

ton that beautiful cream color, or golden tinge, so much admired, and adds to its value some two cents in the pound, provided it is not heated too much; for it may be completely ruined by over-heating. We gin with a fine saw gin. When we start our gin we set some five hands to picking over the cotton before the gin, to pick out the remaining trash that may be left in the cotton, and the yellow ends of bolls, that greatly injure the cotton if suffered to remain and be ginned up with it. We run our cotton through a flue after it leaves the brush. This flue is about eight feet long, and is so constructed that all the dirt and fine trash, in passing over the fingers or ribs of the flue, falls in a box below, and is emptied out once a day. We run our gin extremely slow—so much so that the cotton is not passed from the brush sufficiently hard to throw it out of the flue: consequently, a hand pulls it out of the mouth of the flue. One hand drives the mules, though a boy will answer for that purpose; then the ginner and the five hands picking over, and the hand that pulls it out of the flue, and a boy that hands the cotton to the ginner—making in all eight hands, though most of them are small hands. We do not suffer much cotton to remain in our room that holds the picked cotton, but pack often. We take the greatest care, in packing, not to suffer the cotton to be trod in the box, but run the screw down on it twice or three times, as every time the cotton is trod on it defaces it to some extent. We are very particular to put up our cotton in nice packages, with the best bagging and rope, carefully sewing up the sides and ends. We make three distinct qualities of cotton, as every farmer, I think, should do. We place our name and residence on the first and second quality; on the third quality we put the letter *M.* The past year we made 59 bales, in the following order: 31 marked A. McDonald, Eufaula, Ala., (with 3 F.;) 16 bales, A. McDonald, Eufaula, Ala., (2 F.;) 12 bales marked *M.* The *M* cotton we sold at Appalachicola at 4½ cents; most of the 2 F. we have sold in New York at 7 cents; the 3 F. we have refused 9 cents for, and expect to get 10 cents. It took us something over three months to pick out our cotton out of the field, and about two months to gin it, with nearly as many hands as it took to pick it out, as we gin but little over a bag a day. Thus, Messrs. Editors, you discover that it is a tedious business to make fine cotton; but I think I am amply paid for my pains, not only in money, but what I esteem more—my standing as a farmer.

Your friend and obedient servant,

ALEXANDER McDONALD.

Messrs. Cameron & Fall.

P. S.—Messrs. Editors, I have endeavored to be particular in answering your inquiries as to the plan of making fine cottons. We made last year near five bales to the hand, weighing 490 pounds; but ours is completely the cotton-growing region. This important plant loves a southern sun. If I lived in Tennessee, I would, by taking the same pains with the products that were intended by the Almighty to be reared in that more northern latitude, if I am not greatly deceived, be as successful as I have been with cotton. Agriculture is a great business; it has to be studied as a science. We, as farmers, must procure all the lights that we can, to succeed in our honorable avocation. A. McD.

N. B.—We cultivate, as we have stated, poor pine land. We made last year about 1,000 pounds of cotton to the acre. By a system of manuring

that I have now commenced, I have no fears but that I can double that quantity, and make 50 bushels of corn to the acre. We made, last year, 6,000 bushels of manure: we expect to more than double it this year.

A. McD.

From Wilmer and Smith's European Times, January 4, 1846.

LIVERPOOL ANNUAL COTTON REPORT.

The review of the year 1845 is simple. The fluctuations in fair qualities of upland and Orleans cotton, from the highest to the lowest, have exceeded 12 per cent., and the import, generally, has been profitable. The season opened under favorable auspices. The stock on hand was large, but prices were so low as to inspire confidence. All expectation of an overwhelming import, which had operated so prejudicially in the month of November, and in the beginning of December, 1844, had disappeared before the month of January of the present year, and the result now proves the American crop to have been 2,394,500 bales, exclusive of 25,900 bales from Texas. It is true that there are many, who, in January last, believed this to be an over-calculation, and, under the conviction that the growth would not exceed 2,100,000 to 2,200,000 bales, prices rather advanced in that and the following month. In addition to this motive for action, common both to the speculators and the trade, the announcement of the intended repeal of the duty on cotton furnished fresh stimulus, and the sales were very extensive. But, in spite of this, the month of March, by a combination of circumstances, proved to be unsatisfactory, since, instead of advancing, the market declined $\frac{3}{8}d.$ per lb. The duty of $\frac{5}{16}d.$ per lb. on cotton wool, however, being then taken off, the real difference in money to holders was not important; but as many of them, in the first instance, expected to gain that amount, the disappointment seemed almost equivalent to a loss. In the early part of April, the statements as to crop, which had, as just stated, been gradually diminishing, now began again to increase, and the receipts into the ports seemed to justify the new anticipations. It was for a time in vain that the buying here continued large, and that the probability of dissension between the United States and this country respecting the Oregon territory was again brought more prominently forward by the declaration of both parties in the House of Commons as to the general determination of the legislature not to surrender our early rights to the disputed country. All was unavailing, under the pressure of the heavy stock and increasing supply, to raise prices. On the contrary, they again receded. This state of things, it is true, was only of short duration, for the profits realized by spinners being at least 2$d.$ to 3$d.$ per lb. at the end of April, and in the beginning of May, the decline was again recovered, and the excitement upon the American question seemed to gain fresh force. It is certain that neither then nor any time since has it been generally believed that the discussion would terminate seriously; yet a certain degree of fear has existed, that, previously to any final arrangement, so angry a feeling might be raised as to interpose increased difficulties. The negotiations were now rendered more delicate and critical from the decided manner in which each party had asserted its claim, and with every wish to avoid actual hostilities; yet, in discussions between nations, the slightest untoward incident may lead to open rupture. It is this same sentiment which still prevails, and

which has always more or less entered into the views of holders, throughout the year. The message of the President is of a nature to confirm this impression. Returning, however, to the question more immediately before us, June was a month of large business, though without any advance in price. The only new feature which manifested itself, was that of advices as to the appearances of the coming crop of 1845–'46, which were not propitious. Though the period of the year was far too early to form any correct judgment, yet the plant germinated, it was said, so unfavorably as, in the opinion of many, to furnish a reasonable motive for steadiness in prices. In July, the intelligence continued to be of the same description; and it was then also supposed that the crop would be later than usual. Speculators, encouraged by the facilities of the money-market, as well as by the continued prosperous state of trade, and the lowness of prices, purchased largely on the one hand, whilst the spinners, on the other, deemed it prudent to keep up their stocks to a point beyond their usual quantity. It was the large supply in the port alone which tended to keep the market in check. The weather might have had some little effect at that period; but this was only slightly regarded, though circumstances have since proved of what immense importance was its then character. Before the end of August, all apprehensions as to the harvest, if any were ever seriously entertained, seemed for a time to subside, and the market again improved. The stock of American cotton had reached its *maximum* of 832,000 bales. This amount now began sensibly to diminish, and the month of September was one in which the business transacted was of vast extent. In the beginning of October, in consequence of the alleged deficiency of yield in the wheat crop, and of the injury done to the potato crop in this and other countries, a settled, dull, and anxious feeling began to prevail; and this continued unabated throughout the remainder of the month. November was still more discouraging, and a second advance in the rate of interest to $3\frac{1}{2}$ per cent., by the Bank of England, (the rate of interest had already been raised, on the 16th of October, from $2\frac{1}{2}$ to 3 per cent.,) effectually destroyed all hope of change for the better in the money-market; and with this all prospect of amendment in cotton seemed for the moment to be annihilated. During the present month of December, there has been a regular and steady demand daily; but a tighter state of the money-market, coming, too, at a period of the year when there is always rather a desire, than otherwise, to liquidate existing engagements, and to diminish the amount of responsibility, both on the part of merchants and brokers, had, until counteracted by the advices of the last packet, bringing reduced estimates of crop, operated still further to depress prices, and to throw a gloom over commercial transactions generally. The projected change in the ministry, and the uncertainty of the immediate effect of the measures to be proposed with reference to the opening of the ports for the admission of grain, and the abolition of the corn-laws, have contributed still more to unsettle the public mind, and in the doubt that has been raised, and the hopes and fears which have alternately predominated, trade has suffered, and confidence has been considerably shaken. The railway deposite question, also, which belongs to another part of our subject, has likewise been one of the principal causes of the distrust which has pervaded the moneyed interest, and through this influence essential injury has been done to the holders of cotton.

Having now alluded more especially to the fluctuations in the article itself, other events of the year, as they are more or less indirectly connected

with it, call for a few observations. The first one of these in the order of time, and probably in importance, as it refers to cotton itself, is the abrogation of the whole import duty, which is one of the most remarkable events in the history of commercial policy. It is a measure fraught with wisdom, not only as being in itself of vital importance to the country, but as a precedent for other changes of a like nature. It will tend to give a still greater development to the manufacturing energies of Great Britain, and will better enable us to compete, in common and heavy fabrics, with that very country (the United States) where the raw material itself is produced. It had been a growing complaint, that the duty, which constitutes in coarse goods so heavy a per centage upon the cost, was causing our manufactures to be superseded in the South American markets; and it was to correct the evil in that hemisphere, and to prevent its extension to India, upon which so much of our future prosperity depended, that, seeing the financial state of the country would bear the abstraction, the government wisely abandoned this branch of revenue, though it is certain that, for immediate popularity, other reductions might have been selected, and other taxes taken off, which would have been more acceptable to the multitude. This act of the government cannot be too much commended.

The next point which calls for comment, is the mania in railway speculation during the greater part of the year. The words of the historian of 1720 describe in so accurate a spirit the folly of 1845, that it can hardly be out of place to quote them. Speaking of the South sea and other schemes of that day, he says: "All distinctions of party, religion, sex, character, and circumstances, were swallowed up in this universal concern, or in some such pecuniary project. Exchange alley was filled with a strange concourse of statesmen and clergymen, churchmen and dissenters, whigs and tories, physicians and lawyers, tradesmen, and even with multitudes of women. All other professions and employments were utterly neglected, and the people's attention wholly engrossed by this and other chimerical schemes, which were known by the denomination of bubbles. The sums proposed to be raised by different expedients amounted to £300,000,000 sterling, which exceeded the value of all the land of England. The nation was so intoxicated with the spirit of adventure, that people became a prey to the grossest delusion." By a most valuable synopsis, published in the London Times newspaper last month, it will be seen that 47 completed railway companies had paid up and borrowed £70,000,000; that 118 lines in the course of construction, and for which acts of Parliament had been obtained, required £67,000,000; that for the railways projected, amounting to 1,263 companies, £59,000,000 of deposites would be necessary; so that the total capital invested and required, (taking the amount actually paid up at £54,000,000 in railways completed, and those in course of execution, sanctioned already by Parliament, into account, together with £59,000,000 to be paid of deposites upon new lines,) would be £113,000,000. Thus, to carry out these projects, including the money already borrowed, £590,000,000 would be necessary—the very magnitude of which sum must strike every one as evidencing the highest degree of insanity in any nation which could entertain projects involving such an outlay. The deposite question, as it has been generally designated, arose out of this extraordinary state of things. By the act 1st and 2d Victoria, it is rendered imperative that the deposites upon the undertakings in question should be paid into the Bank of England, to the credit of the Accountant General,

within 14 days after the meeting of Parliament. It is true that the check so opportunely given by the Bank of England, by raising the rate of interest, effectually put an end to many of the schemes; but it was supposed, in the first instance, that a sufficient number had complied with the forms necessary to make the deposite alone £20,000,000. Subsequent information has led to the conviction that this sum was greatly overstated, and that the amount required will not be £10,000,000; but during the time that the process has been going on of weeding out the lines which had not complied with the necessary formalities, great uneasiness has existed in the money-market. The banking interest all along has felt quite unable to explain how the difficulty would be met; and, although certain that, from the total impossibility of complying with the law, there must be some mode of extricating the country from its embarrassment, yet, even now that £10,000,000 only are supposed to be required, the moneyed interest is necessarily upon its guard; for to withdraw this sum, if only for a few days, from the requirements of trade, would be to put a stop to the whole machinery of the circulation, and derange all branches of public financial arrangements.

The President's message, though looked for with great anxiety, has produced less effect than might have been expected. Its tendency by a few is not thought to be unpacific; but the generality of persons consider, notwithstanding its calmness of tone, that there is a determination pervading it which is any thing but amicable in spirit, or generous in feeling. It seems to breathe a decision of purpose hardly concealed by the moderation of its language. Its demands assume conclusions which are most exaggerated; and its harshest and worst feature is, that it seems to close the door, by anticipation, to all interference in a matter which, in case quarrel is to be avoided, can best be arranged by foreign friendly arbitration. It is difficult to suppose that nations so wise and so enlightened as our own and that of the United States should not recoil from the idea of war for the sake of so trifling an object as the possession of a wilderness, separated from both countries by rocks and deserts on the one hand, and by the ocean on the other; but as there is a point beyond which concession would be considered weakness, it is impossible to say what may be the result.

The deductions to be drawn from all the facts before us are, as usual, liable to much uncertainty; and the crop, after all, in the opinion of most persons, is the main point upon which, as far as cotton is concerned, the future depends. There are some who rate this high, and consider that it will reach 2,300,000 to 2,400,000 bales; but there are others, equally well informed, who pretend that 2,200,000 bales will be the *maximum*. Added to this contingency, there is the certainty of a large consumption and a good trade, and the remote possibility of war; but the transactions of this year, as far as regards speculators, have been so unfortunate that it is probable the market will be left very much to the trade for some time to come, and under these circumstances it is rare for prices to improve either very rapidly or considerably. Decline seems considered by every one to be out of the question; but whether or not any material advance is to be experienced, depends so much upon points that are yet doubtful, that to predict an important rise, should it prove to be the case, would be rather a fortunate conjecture than the result of reasoning which at present could be fully justified.

HAYWOOD & M'VICCAR.

DECEMBER 31, 1845.

From Wilmer and Smith's European Times, January 4, 1846.

MANCHESTER MARKET—ANNUAL REPORT.

In addressing you with our two last annual circulars, we had occasion to notice the general fulfilment of the expectation we had held out at the commencement of each period embraced by them, of a satisfactory course of business. Seldom, however, have our prospects appeared of a more propitious character than those which ushered in the past year, 1845. The demand for our manufactures abroad and at home was gradually and steadily increasing, employment of the working population was very abundant, food of all descriptions was plentiful and cheap, capital was accumulating and seeking every channel for employment which offered any fair chance of being a profitable investment; and as our foreign political relations were without the appearance of any immediate interruption, confidence was general throughout the commercial world. With a combination of such favorable circumstances, and with an abundant supply of the raw material, which forms the basis of the staple manufactures of this district, and of which, independently of the large stock in Liverpool, so considerable a portion was also held by spinners and manufacturers, as to prevent the probability of success being gained by any extensive speculation in the Liverpool cotton market—should such be attempted, it was not difficult to conclude that the course of our market would be favorable for some time forward.

For the first two months of 1845 we had a continuance of the favorable aspect which characterized our market at the close of the previous year, and prices gradually, but decidedly, advanced for most of our staples. The months of March and April witnessed a less active state of business—the market being influenced by the long continuance of the frost, (which retarded for a time the usual continental demand,) by unsatisfactory advices from the Bombay and Calcutta markets, and also by an uneasiness which began to be entertained for the settlement with the United States of our claim upon the "Oregon" territory. The effect of these circumstances was a decline in prices generally, and which reached to a greater extent before the end of April than was previously expected. The month of May, however, showed a renewal of the demand, and prices were extremely steady, with a slight tendency upward, which became more decided in the succeeding months of June and July, when a considerable advance took place. In the early part of August, fears began to be entertained as to the result of the harvest, the weather being generally unsettled throughout the country. The month of September was one of critical importance to the maintenance of the prosperity which may be said to have characterized every previous month of the year; the early part of it gave promise of those expectations being realized which were formed upon the improvement of the weather towards the close of the previous month; but these were soon succeeded by renewed fears in consequence of a return of the unpropitious weather, which continued until it became evident that the harvest could not be secured in good condition, and that the yield would be deficient in both quantity and quality. In October a new ground of alarm began to present itself in the unexpected and serious failure in the potato crop, and which not only existed in this country, but extended itself throughout the continent of Europe, besides occurring again in the United States. It was in this month, also, that the Bank of England deemed it necessary to

raise their rate of discounts, for the first time during the past year; and this, accompanied as it was by increased rates of discounts throughout the country, brought on a tightness of money generally, (and especially in the share market,) and led to a sudden and rapid decline in the prices of all shares—many of which became almost totally unsaleable. The effect of this reaction was not confined to scrip shares, but extended also in a smaller but still serious degree to shares in the long-established and dividend paying lines, which declined sympathetically, and often with less discrimination to their respective merits than to the strength or weakness of their holders. The combination of these untoward circumstances could not exist without producing considerable influence upon the state of our own market; and during the month of October a general languidness existed, which was followed, in November, by a sudden and most serious decline in the value of every description of goods and yarns. The difficulties which combined in producing this decline were no doubt much increased by the uncertainty then and still existing as to the manner in which the railway deposites are to be paid over to the Accountant General on the opening of Parliament, and which rendered the bankers unusually tight with their customers; and were also further enhanced by unsatisfactory advices from the United States respecting the "Oregon" question. Towards the end of October, and in the month of November, a general impression existed that government would open the ports, by an order in council, for the admission of foreign grain and provisions, with the view of averting the evils attendant upon the impending scarcity; but as a succession of cabinet councils were held, and broke up without any such determination having been come to, the general gloom and want of confidence was continued and augmented towards the close of the month, and was evidenced in this market by sales being pressed at most sacrificing rates. The same features have since continued with more or less intensity during the month of December, attaining their maximum towards the middle of the month, and during the continuance of the ministerial crisis which succeeded the resignation of Sir Robert Peel and his cabinet. Since his resumption of office, more confidence has been felt throughout the country; and our market, although without any decided improvement in prices, may be considered rather steadier and firmer; for it is felt that he has the power to carry through Parliament such measures as the country in its present critical position requires.

Similar to the course of our own market has been, with little exception, that of the Liverpool cotton market. Throughout the early part of the year, and up to the month of September, spinners and manufacturers purchased freely, although a gradual advance was taking place in prices during that period, and which, notwithstanding the remission of the import duty on the 22d of March, of $\frac{5}{16}$ths of a penny per pound, amounted, by September, to fully $\frac{3}{4}$ths to 1*d.* per pound, average. Upon reference to the Liverpool brokers' circular, we find the trade had taken, up to the 26th of September, 1,151,210 bales, or at the rate of 30,295 bales per week—an excess over the power of consumption, according to the best estimate we can form for the year 1845, of fully 3,000 bales per week. At this period the same unfavorable circumstances, of which we have more minutely traced the operation on our own market, began to have their influence on the state of the cotton market also; and we find, from the same authority, that the quantity of cotton taken by the trade during the remainder of the year, up to the 26th December, amounted to only 245,010 bales, or an average of 18,847 bales

per week; thus making the total quantity taken, from January 1st up to that date, 1,396,220 bales, or a weekly average, for 51 weeks, of 27,377 bales. Notwithstanding the recently diminished supplies taken by the trade as above noticed, we are of opinion that they still hold as large a supply of cotton as they did at the close of the year 1844. In confirmation of this opinion, we would beg reference to the following table, showing the manner in which they have taken their supplies from the Liverpool market for the last two years:

Deliveries of cotton for consumption from the port of Liverpool.

	Weeks	Bales.	Bales.		
1844, Jan. 1st to May 31,	22 weeks,	467,910	or 21,269	per week	From June 1, 1844, to September 26, 1845.*
" June 1st to Dec. 31,	30 "	844,421	" 28,147	"	
	52	1,312,331	25,237	"	
1845, Jan. 1st to Sept. 26,	38 "	1,151,210	or 30,295	per week	
" Sept. 27 to Dec. 26,	13 "	245,010	" 18,847	"	
	51	1,396,220	27,377	"	

* 68 weeks—1,995,631, or 29,348 per week.

In the first twenty two weeks of the year 1844, viz: up to May 31st, and in consequence of the speculation which existed in the cotton market, the purchases made by the trade amounted to only 467,910 bales, or an average of 21,269 bales per week, by which time their stocks must no doubt have been reduced to a very low point. After this period, and up to the 31st of December, 1844, when prices continued rapidly to decline, they took their supplies much more freely; for we find that, for the remaining thirty weeks, they amounted to 844,421 bales, or a weekly average of 28,147 bales; the total quantity taken in the whole year of 1844 being 1,312,331 bales, or an average of 25,237 bales per week, whilst the estimated consumption of the year was about 24,000 bales per week, as we showed in our last annual circular. From these circumstances, and upon reference to the above table, it will be seen that from June 1st to December 31st, 1844, they must for thirty weeks have taken an average weekly supply of about 4,000 bales per week in excess of their consumption; and from January 1st to September 26, 1845, for thirty-eight weeks, allowing of 3,000 bales per week as the increased amount of consumption of 1845 over 1844, they must have still added to their previously large stocks fully 3,000 bales per week more for that period. In corroboration of this view, we would further notice the circumstance shown in the above table, that, from June 1, 1844, to September 26, 1845, a period of sixty-eight weeks, the supplies to the trade amounted to 1,995,631 bales, or 29,348 bales per week; during which time there was every inducement to increase their stocks to as great an extent as they could conveniently hold, from the circumstance of cotton ruling at very low prices; money being abundant, the demand for twist and goods very extensive, and likely to continue so, and, above all, from the increasing abilities of the trade, from the profits they have lately realized, to invest a larger amount of capital in a stock of the raw staple than they were formerly able to do so; the fluctuations to which they were in past years subjected, and from which they occasionally suffered severely,

by the action of speculations in the Liverpool cotton market, rendering it obviously to the interest (as undoubtedly it is becoming the practice of all who have the power) to maintain a large stock of cotton beforehand, so as to take advantage of the most favorable opportunities for making their purchases. The supplies of this material for the coming year appear likely to be abundant, as the advices just received from the United States indicate a probable crop of 2,300,000 to 2,400,000 bales; and as the estimated stock in Liverpool, on the 26th of December last, is 889,970, against 727,660 at the same period of 1844, (an amount greater than ever previously held at that period of the year,) there can be but little grounds for apprehension of any undue excitement in the Liverpool market which can seriously interfere with prices, notwithstanding the speculation going on in America, unless in the event of a war with that country becoming probable.

Having cursorily alluded to the principal features which have characterized the course of our market, and also the cotton market in Liverpool, during the past year, we may now glance at the particulars of our export trade in cotton manufactures. For this purpose, we beg your reference to the following table, showing the amount of exports from January 1st to November 23d, in the years 1844 and 1845 respectively, with particulars of the increases and decreases to the several markets.

[The above table does not include quilting, cotton shawls, lace, hosiery, &c.]

By this table we find an increase in the quantity of yarn exported in the above-mentioned portion of 1845, over the corresponding period of 1844, of 1,768,074 lbs., or about $1\frac{1}{3}$ per cent.; whilst the increase in the export of piece goods during the same period amounts to 45,653,375 yards, or above five per cent. With reference to the exports of yarn, it will be ob-

served that the increases are chiefly to Germany, Holland, and Naples and Sicily, whilst the chief decreases have been to Madras, Calcutta, Bombay, the Levant markets, and Russia. The total amount of increase in the exportation of yarn would appear to be by no means sufficient to account for the comparatively high prices at which all descriptions of yarns have ruled throughout the year, when contrasted with piece goods, and which we have so frequently had to notice in our monthly circulars during the past year. We have previously attributed these comparatively high rates of yarn to the circumstance that, in the years 1843 and 1844, when trade began generally to revive, a much more rapid increase took place in putting down new looms than spinning machinery; which last not only involves more capital, but also requires much more time for construction; and we think the above table bears out the opinion we have before expressed, that the buoyancy of the yarn market was chiefly occasioned by the demand for the supply of the new looms. Referring to the exports of piece goods for the periods embraced in the above table, it will be found that the principal increases are to Chili and Peru, China, St. Thomas, British West Indies, Syria and Palestine, British North America, and the United States; whilst the principal decreases have been to Bombay, Turkey and Greece, Portugal, Egypt, and the Brazils. The total increase in the export of piece goods and twist shows a satisfactory progress in the state of that branch of our trade; but when it is remembered that there has been an increase in the consumption of cotton during the past year, compared with 1844, of probably 150,000 bales, or about 12½ per cent., and that of piece goods to about 5 per cent., there must be a large residue left, either for home consumption or for increase of stocks held on hand. That the latter partially exist at the present moment there can be no doubt; but not to such an extent as in any way to account for the increased consumption of cotton. In point of fact, until the panic came upon our market in the month of October, there might be said to be no stocks of any moment held by manufacturers of any description of goods; and from all we have seen, we have every reason to think that there has been a large increase in the home consumption of our manufacture throughout the year. A similar feature to the above, in the position of the home trade, is exhibited in the following table, compiled from the official accounts of the Board of Trade, of articles entered for home consumption from January 1st to November 5th respectively, in the years 1841 to 1845, inclusive.

From the above table, it will be observed that a decided increase has taken place in the consumption of all the articles specified, and which, it will be seen, embrace all the principal necessary luxuries of life, and upon which $\frac{4}{5}$ths of the total revenue derived from our imports is levied. Such a considerable increase as exhibited in most of the articles here enumerated could only have taken place, or can be maintained, whilst the great mass of the people are profitably employed, and the first necessaries of life are cheap. Whether a similar satisfactory result will be exhibited in the next and in future years, depends much upon the course which our legislature may follow on the important questions which will doubtless come under discussion in the ensuing session of Parliament. The several changes which have of late years taken place in our commercial legislation, indicate a better appreciation of what we conceive to be sound principles than formerly existed. The most important step made in this direction was the partial revision of the tariff during the past year, when the duty upon cotton wool, together with that upon 430 other articles, which yielded but trifling amounts of revenue, and including silk, hemp, flax, dye-stuffs, &c., was totally repealed, and a considerable reduction was made in the sugar duties also. This change in the tariff gave, we believe, very general satisfaction to the country, (and particularly to the commercial classes,) the more especially as it was thought to indicate but the commencement of a policy which would hereafter be more fully developed. In the proposal for a modification of the sugar duties, it was estimated that the reduction in price would lead to an increased consumption of that article, and that the total amount for the year would reach 250,000 tons, or 5,000,000 cwt., the largest previous consumption being for the year 1844, when it amounted to 207,000 tons, or 4,140,000 cwt. The above table, although embracing but ten months of the year, and only eight months during which the new scale of duties has been in operation, exhibits already an increase in the consumption over the entire year 1844; and we can have little doubt that the consumption of the whole year, under the new duties, will exceed the estimated amount. We cannot, whilst upon this subject, refrain from expressing a hope that, at no distant period, the distinction which has been continued in the late tariff, and has excluded us from availing ourselves directly of the supplies of sugar afforded by the Brazilian market and by the Spanish colonies, will be discontinued; for already has a spirit of retaliation been shown by the Brazilian government, in the increased disadvantages under which our trade has been placed, and by the curtailment of the political and civil privileges formerly enjoyed by British subjects trading with that country. In concluding our remarks upon the recent changes in the tariff, we are strongly reminded of the necessity which exists of as early a revision of the tea duties as practicable, so that we may reap the full advantage of the liberal and enlightened treaty made with us by the Chinese. Although many articles of returns will continue to offer, and probably in increasing quantities, from the Chinese ports with which we carry on trade, it is pretty evident that, for a considerable time at least, the principal article in payment for our exports must be tea—the only present limit being that of our consumption, and the extension, therefore, necessarily resting with ourselves only. When it is considered the duty now levied upon tea amounts to 2*s.* 3*d.* per lb., whilst the price of common Congon, which furnishes about two-thirds, probably, of the whole amount consumed, is now only 10*s.* per lb., the extent to which the duty enhances the cost to the consumer will be

readily understood. Although, since the year 1841, the above table shows an increase of consumption of nearly 25 per cent., and a proportionally larger increase than any other leading article specified, this only indicates the more strongly the growing favor of the population for this luxury, and the probability that the consumption would be very greatly augmented by a liberal reduction in the duty.

In looking to the future prospects of our market, it is impossible to form a very decided opinion—so much being immediately dependant upon the future policy of our legislature, the course of which, under existing circumstances, it would be almost idle to speculate upon. We therefore refrain from offering any prospective remarks of this nature.

GEORGE FRASER, SON, & CO.

January 1, 1846.

From Wilmer & Smith's European Times, January 4.

COTTONS.

Havre, *December* 31.

During the last sennight our market has worn a decidedly improved appearance, both as to the amount of business transacted and to the increased stiffness in prices, which may be considered a shade higher than our previous quotations. The formation of the British ministry has, generally speaking, created a favorable impression, and confidence seems daily to be gaining ground. The demand has therefore been rather animated, and to a good extent; and amongst the sales was a cargo of 1,700 bales expected from New Orleans, by the Osceola, taken at f. 67 all round. At this dull season of the year it is not usual to look for any great activity; but as our stock is far from large, and the internal districts are but scantily supplied, it is more than probable that early in the ensuing year the trade will be coming forward more freely, and that the transactions will then assume a spirited character. The receipt of the President's message, which has long been expected with a certain degree of anxiety, seems to have produced little impression, for, although the tone is not in a conciliatory strain, it has given no rise to any serious apprehensions as to the future. Taking a retrospective view of the year that has just closed, we find that the situation of our market has, upon the whole, been unstable; for, notwithstanding the moderate stock of cotton on hand during the last twelvemonth, speculation has, at no period, been extensive, nor of long duration; and if, in consequence of an unusual briskness, holders have had high pretensions, buyers have immediately withdrawn from the field, under the plea of the large stock in Liverpool, and the unprosperous state of the manufacturing districts. Latterly, the high price of breadstuffs, added to the fears of a dearth and of a financial crisis, have acted very prejudicially to commerce in general; but these were evidently much exaggerated, and the public mind has now completely recovered from the panic. It must, however, be admitted that if a portion of the working districts have been in a comparatively satisfactory condition, the reverse has been the case with others; and it is only to the trifling importance of a raw material that can be ascribed the steadiness in prices for some time past. By the Argo, we received yesterday

New York dates to the 11th inst., and we are hourly expecting those of the 15th by the Cambria steamer arrived at Liverpool. We now refer to the subjoined table, showing the movement in our port since the commencement of this year contrasted with former statements.

The following were the sales effected, viz:

2,852	bales	New Orleans, duty paid - - - -	f. 47 to 76
409	do	Mobile - - - - - -	52 to 68.50
2,250	do	Upland - - - - - -	52 to 70
1,800	do	New Orleans, to arrive, duty paid - -	— to 67
650	do	Peruvian - - - - - -	— to 76
7,961	bales.		

The imports amount to 14,245 bales.

Imports, deliveries, and stock in France, from 1st January to 30th November, for the last three years.

LIVERPOOL, *December* 31, 1845.

GEORGE HOLT & CO., *Cotton Brokers.*

APPENDIX No. 12.

SILK.

From the New York Farmer.

Mr. Clark, (to whom we are indebted for many valuable facts,) in speaking of the silk culture in America, divides it into three periods. He says: "The first period may be said to have continued from the first introduction of the silk culture in North America, in 1623, to the close of the revolutionary war, in 1783, or for 160 years.

"The second epoch is from that event to the time when there was in this country public evidence of decisive knowledge of the multicaulis (Chinese) mulberry—or to July, 1830.

"The second epoch, then, in the history of the American silk culture, commenced in 1783. Notwithstanding the desolation generally introduced by war, which, where internal, has too frequently a continued effect, the silk enterprise was, though somewhat gradually, renewed. It was precisely at this period (1783) that the legislature of Connecticut, induced by the exertions of Dr. Aspinwall and the Rev. Dr. Styles, granted a bounty on mulberry trees and raw silk. In 1789, 300 pounds of raw silk were made in Mansfield, which in 1793 produced 365 pounds of raw silk. In 1810 the sewings and raw silk of New London, Windham, and Tolland were valued by the United States marshal at $28,503, exclusive of the amount of domestic fabrics; and double this entire amount is said to have been manufactured there in 1825. So popular indeed had silk products become about this period, that they were readily taken then as a circulating medium."

About the period of the last war, a good degree of interest existed, and many were successfully engaged in its culture. Mr. Samuel Chidsey, of Cayuga county, New York, is said to have raised, manufactured, and sold $600 worth of sewing silk in a year, and several establishments were in successful operation in Tennessee, Kentucky, and Illinois. So much interest existed at this time, that members of the House of Representatives were strongly in favor of affording govermental encouragement, and a bill was accordingly introduced, and favorably received, recommending the appropriation of $40,000 for the establishment of a Normal School for silk reeling in Philadelphia, for the gratuitous instruction of sixty young men, for two years, in the various branches of reeling, manufacturing, and dying silk. For some reason, this bill received no final action until 1832, when it was defeated by a small majority.

The third epoch, according to Mr. Clark, commenced at the time when the multicaulis, or China mulberry, became sufficiently known to induce its propagation, or about 1831–'32. This was a brief era, characterized by the wildest and most erroneous theories. It would require volumes to detail the thousand and one schemes resorted to for creating and sustaining what has been termed the *mulberry excitement—multicaulis speculation.*

The history of this visionary period is too fresh in the minds of most of our citizens to need review.

From the Southern Cultivator.

A BRIEF HISTORY OF THE SILK CULTURE IN GEORGIA.

By the Rev. William B. Stevens, of the University of Georgia. [From Harris's Memoirs of Oglethorpe.]

One of the principal designs which influenced the settlement of Georgia was the hope of thereby creating a silk-growing province, where that material for which England had so long been indebted to France, Italy, and China, could be produced in this colonial dependency.

As early as 1609, the subject engaged the attention of the adventurers to Virginia, and in a pamphlet called "Nova Brittania offering most excellent fruites by planting in Virginia," published that year, the writer says: "There are silke-wormes and plenty of mulberie trees, whereby ladies, gentlewomen, and little children, (being set in the way to do it,) may bee all imploied with pleasure, making silke comparable to that of Persia, Turkey, or any other." In 1650, Mr. Samuel Hartlib published a work entitled "Virginia Discovery of Silk Wormes, with their Benefits," in which he endeavored to show that the raising of silk was a thing very practicable in Virginia, and even asserted that as a staple it might be made superior to tobacco; in which opinion he was confirmed by the judgment of several others. That they made some advances in this culture is evident from the fact that the coronation robe of Charles II, in 1660, was made of silk reeled in that colony; and even so late as 1730, three hundred pounds of the raw material were exported from Virginia. Tobacco, however, soon assumed and maintained the ascendency, to the exclusion of this more useful and beautiful produce.

In 1703, Sir Nathaniel Johnson introduced the silk culture into South Carolina, but the astonishing success which rewarded the casual introduction of rice into the plantation, about eight years before, precluded a just interest in the undertaking, and, as a public and recognised commodity, it soon came to nought, though several persons, more for amusement than profit, still gave their attention to it; and as late as 1755, Mrs. Pinckney, the same lady to whom the province was indebted for the first cultivation of indigo ten years before, reeled sufficient silk in the vicinity of Charleston to make three dresses, one of which was presented to the princess dowager of Wales, another to Lord Chesterfield, and the third (says Ramsay, who narrates the circumstance) "is now (1809) in Charleston, in the possession of her daughter, Mrs. Horrey, and is remarkable for its beauty, firmness, and strength."

But notwithstanding these failures and the known difficulty of introducing a new branch of agriculture into a country, as was evidenced by the compulsion which was necessary by Henry IV to introduce it into France against the united voices of the merchants, traders, and even in opposition to the Duke of Sully, and also the indifference manifested in England—notwithstanding the able proclamation of King James on the subject, commending its cultivation—the trustees for the settlement of Georgia determined to make one more effort, which, if successful, would enrich both the province and the mother country. The views which they entertained, however, of making Georgia supplant every silk-growing country, were extravagant and erroneous. They expected, in fact, to supply all Europe, and to produce an article of equal strength, beauty, and value, with any made

on the continent. The Piedmontese, thought they, who pay half their silk for the rent of the mulberry trees and the eggs of the worm, or the peasants of France, burdened with political difficulty and stinted for conveniences, could not cope with the settlers of Georgia, where the mulberry trees (morus aloa) would grow in the greatest luxuriance; where timber for their fabrics was no expense; where room was abundant, and the reward sure. By this transfer, in addition to a direct saving to England of over £500,000 which she paid for this article to foreign countries, twenty thousand people were to find employment in rearing it in Georgia, and as many more at home in preparing it for market.

Among the first emigrants who sailed with Oglethorpe, from England, in November, 1732, was Mr. Amatis, from Piedmont, who was engaged by the trustees to introduce the art of silk-winding into the colony, and who, for that purpose, brought with him several Italians and some adequate machinery. White mulberry trees were planted in a portion of land on the eastern border of the city, called the trustees' garden; eggs were hatched, and silk spun "as fine as any from France or Italy." They soon, however, came to a mutual rupture, and the whole process was for a time suspended by the treachery of those employed, who broke the machinery, spoiled the seed, destroyed the trees, and then escaped to Carolina. Sufficient, however, had been wrought to test its value, and they were not discouraged by this inauspicious commencement. The trustees still adhered to their design, and, the more effectually to advance it, required of every settler that there should be on his grant ten mulberry trees to each acre.

Mr. Camuse and his wife, both Italians, with their two children, and two other individuals, were now intrusted with this business, in which they were continued six years; the first two at a salary of £60 per annum, and the last four at £100, besides the rent of a dwelling-house and garden.

In June, 1734, General Oglethorpe carried eight pounds of raw silk, the first produced in Georgia, to England, which was followed by a small trunk full of the same article on the 2d of April, 1735, and, after being made into organzine by the engine of Sir Thomas Lombe, at Derby, who said that it "proved exceedingly good through all the operations," was sent up to London on the 14th of August, 1735, when the trustees, together with Sir Thomas Lombe, waited on her Majesty Queen Caroline, and exhibited to her the elegant specimen of Georgia silk. The Queen selected a portion of this parcel to be wove into a pattern; and, being again waited on by these gentlemen and Mr. Booth, the silk weaver, on the 21st of September, she expressed "a great satisfaction for the beauty and fineness of the silk, the richness of the pattern, and at seeing so early a product from that colony;" and to express her pleasure at such a favorable result, a complete court dress was made from it, and on his majesty's next birth day she appeared at the levee in a full robe of Georgia silk.

On the return of Oglethorpe, in 1735, he renewed his endeavors to bring it into active operation. For the purpose of obtaining a sufficient quantity of seed, he allowed no silk to be reeled that year, but let the worms deposite their eggs. He required, also, that the Italian women should teach a number of the colonists, and thus render general the knowledge they could impart. The Saltzburgers at Ebenezer were the most forward to adopt his views; and in March 28, 1736, Rev. Mr. Bolzius gave one tree to each inhabitant as a present from Oglethorpe, and two of his congregation were instructed in the art of reeling by Mrs. Camuse. But though Oglethorpe

gave Mr. Bolzius trees, silk-worms, and a book of instructions, yet he confesses that he felt no interest in the business, nor inclination to pursue it.

In July, 1739, Mr. Samuel Augspourger carried over a parcel of raw silk which he received from Mr. Jones, the trustrees' storekeeper in Savannah, and which was declared by eminent judges to be "equal to any Italian silk, and worth full twenty shillings per pound."

On May 11, 1741, Mr. Bolzius, in his journal, states that "twenty girls, during the last two months, succeeded in making seventeen pounds of cocoons, which were sold on Friday last, at Savannah, for £3 8*s*." During this year General Oglethorpe advanced to Bolzius £5 for procuring trees, for which sum he obtained twelve hundred, and distributed twenty two to each family in his parish.

On May 1, 1742, fourteen pounds and fourteen ounces were sold, which brought £2 19*s*. 6*d*. Nearly half of the silk-worms died at Savannah, owing, as was then supposed, either to poison dew or warm weather.

On December 4, 1742, General Oglethorpe sent five hundred trees to Ebenezer, with the promise of more, if required. The indifference of the good Mr. Bolzius had by this time passed away, and he was now a zealous advocate for its extension. A machine was erected near his house, and two women succeeded very well, by which the people were stimulated to renewed exertions, and a public filature was contemplated. The enterprise of these Germans seemed to excite the envious disposition of Mrs. Camuse, with whom had been placed two women from Ebenezer; but the conduct of Mrs. C. in withholding information rendered their acquirement inadequate, and Mr. Bolzius withdrew them from her charge. The first parcel of silk made was sent to the trustees, who expressed themselves pleased with its quality. In 1745, the weight of cocoons was two hundred and fifty-three pounds, and of spun silk sixteen and three-quarters. In 1746, the weight of cocoons was three hundred and forty-four pounds, and of spun silk eighteen pounds. Early in this year a machine for winding, and coppers for baking, together with appropriate treatises on the art, were sent over by the trustees, but the people were indifferent and apathetic.

The Germans, however, were as active as formerly, and Mr. Bolzius, in a letter to Von Munch, dated May 6, 1747, says, that "the people last winter planted more mulberry trees than for thirteen years before," for which he promised them a bounty of one shilling for every tree which yielded one hundred pounds of leaves. The silk balls raised at this place this year were over four hundred pounds, three hundred and sixty-six pounds of which sold for £36 12*s*. 10½*d*. The amount raised in the whole colony was eight hundred and forty-seven pounds of cocoons, and sixty-two pounds of spun silk. In 1748, the Saltzburgers reared four hundred and sixty four pounds, but their small trees were destroyed, and some of the larger ones injured by the late frost. They, this year, succeeded admirably in spinning twenty-four pounds of raw silk, the want of a chimney and proper basins, which had impeded them before in their rude building, having been remedied. The president, writing to secretary Martyn, December 11, 1746, says: "The fundamental cause of its stagnation is, the unaccountable backwardness of some of our dames and damsels to employ themselves in attending to the worms during the time of feeding, which I have frequently taken notice of, and it cannot be imputed to the want of leaves."

During the same period only thirty-four pounds of spun silk were raised by the trustees' agent in Savannah. Mr. Bolzius, under date of February

15, 1749, thus writes: "The weather being now warm and pleasant, the mulberry trees have put forth their young leaves, and our people are now turning their minds towards making of silk;" and then, after expressing his surprise that so few were disposed to this culture, adds: "One reason for this reluctance is ascribed to the circumstance that, by ordinary labor, about two shillings might be obtained per day, whereas scarcely a shilling could be earned in the same time by the silk concern." Seven hundred and sixty two pounds of cocoons were raised, and fifty pounds thirteen ounces spun silk, and there were two machines erected in Mr. Bolzius's yard which drew off twenty-four ounces per day. On the 29th September, 1749, the trustees promised £2 to every woman who shall make herself mistress of the art of winding in one year. And they also gave Rev. Mr. Bolzius permission to erect ten sheds, with clay furnaces, at an expense of not more than £2 each, and ten machines for reeling, at thirty shillings each, which he says could be made better than those at Savannah for £3: they also sent them ten basins; and the good Germans felt the impulse of this substantial encouragement. In 1750, though the people in other parts of the colony mostly relinquished the silk culture, the inhabitants of Ebenezer continued vigorously employed and interested in it. On the 2d of June they received ten kettles from the trustees, one of which, and a reeling machine, were given to each mistress in the art of spinning, and two of the best artisans received £5 for giving instruction to fourteen young women; to each of whom was bestowed £1 for attention and industry.

Over a thousand pounds of cocoons were raised at Ebenezer, and seventy-four pounds two ounces raw silk made, producing (the price being then thirty shillings) over £110 sterling. As illustrative of the luxuriant growth of the mulberry, it may be interesting to state that two trees in front of the parsonage, ten years old, measured three feet eight inches in circumference. In December, of this year, eight more copper basins were received, and public confidence in the success of the undertaking seemed revived, notwithstanding Mr. Camuse and family had left the province and settled at Purysburgh, in South Carolina.

On the 25th December, 1750, Mr. Pickering Robinson, who, together with Mr. James Habersham, had been appointed, the preceding August, a commissioner to promote more effectually the culture of silk, arrived in Savannah.

Mr. Robinson had been sent to France, at the expense of the trustees, to study the management of filatures, and the necessary process for preparing the article for market, and thus, though no operative, was qualified to take the directorship of so important a branch of industry. His salary was £100 per annum, £25 for a clerk, and a tract of land was also granted him, which, in 1763, sold for £1,300.

Mr. Robinson brought with him a quantity of silk-worm seed, but all failed save about half an ounce. The commissioners determined at once to erect a filature, which should be a normal school to the whole province; and it was their opinion that it would be "a sufficient nursery to supply, in three or four years, as many reelers as will be wanted, when we make no doubt of many private filatures being erected, which can only make their culture a general staple." The dimensions were thirty six feet by twenty, rough boarded, with a loft or upper story for the spreading out of the green cocoons. It was commenced on the 4th of March, 1751. On the 1st of April, the basins were put up, and on the 8th of May the reeling

began. To encourage the colonists, the trustees proposed to purchase all the balls, and wind them at their own expense, and paid from 1*s.* 6*d.* to 2*s.* 4*d.* per pound for green cocoons. The commissioners separated the cocoons into three sorts: 1st, perfect cones; 2d, the spungy and fuzzy; and, 3d, the spotted, stained, and dupions. This management, however, gave great offence to some of the residents in Savannah and Purysburgh, and Messrs. Robinson and Habersham requested the vice president and assistants to determine the respective prices, and publicly announce the same, which they did on the 26th April, by a proclamation; wherein, by way of bounty, they promised to pay for cocoons, delivered at their store in Savannah, the following sums, namely: for cocoons made by one worm, hard, weighty, and good substance, 2*s.* per pound; for the weaker quality, pointed, spotted, or bruised, 1*s.* 3*d.*; for dupions, (those made by two worms,) 6*d.*; for raw silk, from first quality cocoons, 14*s.* per pound; for that made from second quality, 12*s.*; the product of the double cones, 6*s.* per pound; and they also offered, if delivered at the filature, for best cocoons, 3*s.* 6*d.*; for middling, 1*s.* 8*d.*; and for inferior, 1*s.* 1*d.*; a series of prices truly astonishing, when we reflect that the real merchantable worth of a pound of cocoons is scarcely ever 6*d.*

Experiments were made at the filature to ascertain the relative quantity of each of these qualities in a given weight of cocoons, and the results were, that in fifty pounds of green cocoons there were twenty-seven pounds of the first sort, ten pounds four ounces of the second, and twelve pounds twelve ounces of the third. After curing or baking, these fifty pounds weighed only forty-six pounds five ounces, showing a loss in ponderosity of nearly eight per cent. Besides the arrangement above specified, the cocoons were still further divided for the purpose of reeling into white and yellow, and these again subdivided into five each, namely: 1st, hard and weighty; 2d, little woolly and weaker; 3d, very woolly and soft; 4th, spotted and much bruised; 5th, double worms.

Mr. Camuse, son, and daughter, who, it appears, gave the commissioners no little trouble by their perverse conduct, returned to Savannah, and were engaged to labor at the filature at three shillings per day; at which Mr. Habersham exclaims, "monstrous wages!" The reelers now advanced with much proficiency, and five of them, on the 16th of May, wound off eleven pounds of cocoons each. The proportion of raw silk to the cocoons appeared, on a variety of trials, to be nearly in this ratio:

May 10, 1751,	55 lbs. cocoons,	1st quality,	produced	$117\frac{7}{8}$	ounces.
" 11,	" 8	"	"	$\frac{6}{9}$ pr thread,	$18\frac{1}{2}$	"
" 13,	" 11	"	"	produced	$21\frac{1}{2}$	"
" 15,	" 55	"	2d "	"	109	"
" 18,	" 20	"	"	"	24	"
" 22,	" 15	"	1st "	"	$20\frac{3}{4}$	"
" 22,	" 10	"	2d "	"	$13\frac{1}{2}$	"

The whole amount of cocoons raised in the province was six thousand three hundred and one pounds, of which two thousand pounds came from Ebenezer, and four thousand pounds were made at Whitefield's orphan house. Two hundred and sixty-nine pounds and one ounce of raw silk, and one hundred and sixty-one pounds of filogee, were prepared, notwithstanding over three hundred and eighty pounds were lost by vermin, fire, and mould. The expense of the culture was large this year, owing to the

erection of the filature, &c., which swelled the sum to £608 9s. 8½d. sterling. The private journals at that day, kept at Savannah and Ebenezer, acquaint us, in some measure, with the arduous nature of the commissioners' labors, and the difficulties they encountered from the want of funds, the intractableness of laborers, the novelty of the attempt, the imperfections of machinery, and the bitter opposition of those who should have sustained and encouraged them. The public duties of Mr. Habersham prevented his constant attention to this business; but the whole time of Mr. Robinson was devoted to the filature, directing the sorters, aiding the novices, advising the reelers, and in every way exerting himself to obtain success. His engagement with the trustees expired on the 30th of August, 1751; but finding that his intended departure depressed the friends of the culture, he was solicited by the local government to remain another year, and, generously sacrificing private to public interests, he complied with their request. Mr. Habersham thus speaks of Mr. Robinson: "I think him the most prudent, as well as the most capable person I ever knew to undertake such a work, and if he could be continued here, I doubt not but that he would turn out a number of well instructed reelers, who would be able to conduct filatures at Ebenezer, Augusta, and other parts of the province." So great was the confidence which the trustees had in him, that he was appointed an assistant in the government at Savannah; an honor which he declined, and in the same letter stated: "If due encouragement be not given to the culture of raw silk for the term of at least fourteen years, I positively cannot think of settling in America." These gentlemen recommended the building of a house, sixty feet by twenty-six, as a cocoonery, great loss having been experienced for the want of such a structure.

In 1752, Mr. Robinson returned to England, and his place was partially supplied by Joseph Ottolenghe, a native of Piedmont, and a proficient in his art, who came to Georgia on the 18th of July, 1751, and took charge of the filature in April, 1753. In a letter to secretary Martyn, dated September 11, 1753, Mr. Ottolenghe says that "there were fewer cocoons raised this year, as the worms mostly hatched before the trees leaved, and that 'the people were willing to continue the business.'" One hundred and ninety-seven pounds of raw silk were made this year, and three hundred and seventy-six pounds in 1754, besides twenty-four pounds of filoselle. The people of Augusta became interested in this manufacture, and entered with considerable spirit into the undertaking, promising to send hands to Savannah, yearly, to learn the art of reeling: their enthusiasm, however, soon evaporated.

On the 29th of March, 1755, a certificate signed by thirty-nine eminent silk throwsters and weavers was given to the "commissioners for trade and plantations," stating that, after examining three hundred pounds of raw silk, imported from Georgia, "we do sincerely declare that the nature and texture is truly good, the color beautiful, the thread as even and as clear as the best Piedmont (called wire silk) of the size, and much clearer and even than the usual Italian silks;" and furthermore, "it could be worked with less waste than China silk, and has all the properties of good silk, well adapted to the weaver's art in most branches."

In 1755, five thousand four hundred and eighty-eight pounds of cocoons were raised, and four hundred and thirty-eight pounds of raw silk spun. The good effects of the filature were now happily evident in the increased interest of the planters in the subject, who sent both their daughters and

young negroes to acquire the art of reeling. In 1756, three thousand seven hundred and eighty three pounds and one ounce of cocoons were received at the filature, and two hundred and sixty-eight pounds of raw silk reeled.

The liberal policy of the commissioners, who had no private ends to answer, caused them to recommend the establishment of additional filatures, and in their letter to the trustees, June 12, 1751, they advise the erection of one at Ebenezer, and another contiguous to Savannah; but Mr. Ottolenghe opposed this course, and arrogated to the one in Savannah the entire monopoly of the culture. Jealousy appears to have been very conspicuous in Mr. Ottolenghe's character, and his opposition to the Saltzburgers and depreciation of their efforts arose from this suspicious trait. He aimed to render himself solely necessary, and aspersed every thing which seemed to militate with his fancied superiority. This appears not only from letters of Governors Reynold and Ellis, but from his own correspondence, where this caution and fear of rivalry are plainly discernible. His course gave offence to the Ebenezer people, who had already erected a filature in their village; who had been at a great sacrifice to send their wives and daughters to learn the art of reeling in Savannah, and who had hoped to carry on the manufacture under their own supervision, and for their own benefit. Mr. Ottolenghe, however, overruled their views, and required all cocoons to be delivered at Savannah, and to be reeled there. Each basin at the filature had two apprentices, besides others who were employed in sorting the balls, &c., and the various operations connected with the trade employed nearly forty persons.

In 1757, over five thousand pounds of cocoons were received at Savannah, and three hundred and sixty pounds of raw silk spun, which, says Governor Ellis, would have been more if the eggs had not failed; and in a letter dated 11th of March, 1757, he says: "The raising of silk seems to be no longer a matter of curiosity; it employs many poor people, and is approaching towards a staple."

Seven thousand and forty pounds of cocoons were deposited in the filature in 1758; but while the friends of this business were rejoicing in the assured success of their experiment, they were saddened by the destruction of the filature, which took fire on the 4th of July and was totally consumed. The wound silk which had not yet been shipped, amounting to three hundred and fifty pounds, was saved, but several thousand weight of silk balls, together with much of the reeling apparatus, were destroyed. Another and more capacious building was immediately erected, and was ready for use the ensuing season.

In 1759, ten thousand one hundred and thirty-six pounds of cocoons were raised in Gorgia, four thousand pounds of which were from Ebenezer, and the proceeds of their culture alone, for the season, reached £700 sterling. The opinion of those engaged in the culture, as expressed to Dr. Jared Elliott, was, "that it was more profitable than any other ordinary business."

The cocoons delivered at the filature in 1760 weighed seven thousand nine hundred and eighty-three pounds, and there were spun eight hundred and thirty nine pounds. Mr. Ottolenghe was now honored with the full appointment of "superintendent of the silk culture in Georgia," with a salary appropriate to his station.

Five thousand three hundred and seven pounds of cocoons, and three

hundred and thirty two pounds of raw silk, were produced in 1761. Governor Wright, under date 13th of July, says: "The greatest appearance that ever they had here was destroyed in two nights' time, by excessive hard and unseasonable frosts, and there is likewise a degeneracy in the seed, as Mr. Ottolenghe tells me." These frosts occurred on the 5th and 6th of April. Parliament, this year, made a grant of £1,000 towards defraying the expenditure for the silk culture, and it was annually renewed until about 1766. By means of this gratuity, Mr. Ottolenghe was enabled to give a high price to the rearers of cocoons, and thus sustain the encouragement so judiciously commenced.

In 1762, fifteen thousand one hundred and one pounds of cocoons were delivered at the filature, and one thousand and forty eight pounds of raw silk reeled, which Mr. O. declared to be the finest and best silk ever produced in Georgia.

The year 1763 showed an increase of cocoons, but a decrease of silk, there being fifteen thousand four hundred and eighty-six pounds of the former, and only nine hundred and fifty three pounds of the latter. The occasion of this disparity was a season of cold, rainy weather towards the close of April, by which the later cocoons were injured, and rendered almost useless.

There were delivered at the filature, in 1764, fifteen thousand two hundred and twelve pounds of cocoons, notwithstanding the season was so unfavorable that Governor Wright mentions the case of one man, who expected to make from five to seven hundred pounds, who only succeeded in raising one hundred pounds of cocoons. Eight thousand six hundred and ninety five pounds were sent by the Saltzburgers, and the whole amount yielded eight hundred and ninety eight pounds of raw silk.

In addition to the grant of Parliament, a society instituted in London for the encouragement of arts, manufactures, and commerce offered certain premiums for the advantage of the British American dominions, among which were—

"For every pound of cocoons produced in the provinces of Georgia and South Carolina, in the year 1764, of a hardy, weighty, and good substance, wherein only one worm has spun, 3*d.*; for every pound of cocoons produced in the same year, of a weaker, lighter, spotted or bruised quality, 2*d.*; for dupions, 1*d.*" These premiums were to be paid under the direction of Mr. O., with proper vouchers that the same were raised in either of the provinces specified.

It was agitated, in 1765, to reduce the price of cocoons from 3*s.* to 1*s.* 6*d.* per pound, a measure which produced much dissatisfaction; and, as a consequence, there was a considerable falling off in the amount of balls and silk, only twelve thousand five hundred and fourteen pounds of the former, and seven hundred and twelve pounds of the latter, together with seven hundred and twenty pounds of filosele, being produced. To prevent the depression consequent on this reduction, Governor Wright suggested that instead of so much per pound, as formerly, the ten largest quantities should receive, the highest £50, the next greatest parcel £45, and so on, gradually decreasing with the decrease in weight, until you reach the lowest quantity, to which £10 would be awarded: thus, while the expense would be greatly lessened to the trustees, the stimulus of reward would be sufficiently sustained. This advice was not adopted, though, owing to the urgent remonstrances of those best acquainted with the business, the

reduction in the bounty was only 9*d.* instead of 1*s.* 6*d.* On the 25th of April, 1765, the following order was published in the "Georgia Gazette:"

"Notice is hereby given to all whom it may concern, that, by direction of the right honorable the lords commissioners of trade and plantations, the price usually paid for cocoons is now reduced, and that no more than 2*s.* 3*d.* per pound will be paid for cocoons raised in this province, and delivered at the public filature, this season.

"By order of his excellency the governor.

"GEO. BAILLIE, *Commissary.*"

This bounty was still further reduced in 1766, when, by order of the board of trade, only 1*s.* 1*d.* was paid per pound. The dependence of this culture on the weather was signally instanced this year, from the fact that though many who had hitherto raised cocoons abandoned it at the reduction of the bounty, yet such a large crop had never been produced before; over twenty thousand three hundred and eighty pounds of cocoons being delivered at the filature, which, however, only produced one thousand eighty nine pounds of raw silk, and eight hundred and fifty pounds of filosele. This amount of reeled silk was not at all proportionate to the weight of the cones, resulting, as Mr. Ottolenghe said in a letter to Governor Wright, October 2, 1766, "to the badness of the seed, and consequent inferiority of the worms." In 1760, the cocoons weighed only seven thousand nine hundred and eighty-three pounds, and yet eight hundred and thirty-nine pounds of raw silk were spun; at which rate, the product this year should have been about two thousand pounds.

On the 26th of June, Henry Kennan made proposals to the board of trade for carrying on the filature, but they were of a nature not at all advantageous to the culture; and Governor Wright, in his reply, on the 21st of October, disapproved of the plan, and exposed the fallacy of his scheme, which was in consequence abandoned.

In 1767, ten thousand seven hundred and sixty-eight pounds of balls were raised, and six hundred and seventy-one pounds nine ounces of raw silk spun; the decrease of cocoons being caused, first, by withdrawing of the Purysburgh cocoons, which last year amounted to five thousand five hundred and fifty-one pounds; and, second, by the reduction of bounty; so that while last year the cocoons were delivered in by two hundred and sixty-four different persons, only one hundred and sixty individuals were this year devoted to the culture. The silk, however, was of a better quality, and sustained its high reputation in the London market.

In 1768 another plan was proposed by Mr. Delamar, "in order the more effectually to establish the growth of raw silk in America." His proposal was to pay a bounty of 20*s.* per pound on every pound of good, clear, raw silk imported from any of his Majesty's dominions in America, to be paid on the price such silk might sell for at public sale in London; at the expiration of ten years ten per cent. bounty was to be allowed; the ensuing five years at five per cent., after which time the bounty was to cease. This was the general feature of his plan. It was not, however, adopted, though in many respects its provisions were highly judicious and appropriate.

But this branch of industry and commerce was fast waning before the increasing culture of more sure and lucrative products, and only one hundred and thirty-seven different persons brought cocoons to the filature this year. Governor Wright, in his official letter to the Earl of Hillsborough,

July 1, 1768, says: "I am persuaded that few, or none but the very poorer sort of people, will continue to go upon that article. Several substantial persons, who did mean to make it an object when the price was higher, have, to my knowledge, given it over. The reason, my lord, is evident; for people who have their fortune to raise or make will always turn themselves in such a way, and to the raising and making of such commodities, as they think will answer best; and it is very clear to me that those who have negroes may employ themselves and negroes to better advantage, &c., than by raising cocoons at 1*s.* 6*d.* per pound, although that is, as I have said, 7, 8, or 9*d.* more than they are intrinsically worth."

Cluny, in his "American Traveller," printed in London, 1769, says: "The climate of Georgia has been found to agree, in every respect, with the silk-worm." Experience, however, proved that the climate was not sufficiently equable to secure permanent and continued success. Governor Wright, in the letter quoted above, says "the variable and uncertain weather in spring makes it precarious," and facts amply confirm this statement. Only five hundred and forty-one pounds of raw silk were made this year; a smaller amount, with one exception, than had been produced for ten years. In 1769, the quantity was still more decreased, both from the reluctance of the people to raise worms and the unfavorable weather in spring. Governor Wright, on the 20th of June, 1769, says: "We had a most extraordinary prospect till the middle of April, when I thought every thing safe; yet we had very cold rains on the 17th and 18th, which were succeeded by hard, black frosts on the 19th and 20th, and destroyed a great part of the worms, and will reduce the silk very much."

The silk business was now on the irretrievable decline, though it still maintained a nominal existence, and received the encouragement of Parliament. The special bounty which had hitherto been paid on cocoons, over and above their merchantable value, was suspended, and, by a statute of 9 George III., c. 38, a premium of twenty-five per cent. from the 1st of January, 1770, to the 1st of January, 1777; of twenty per cent. from the 1st of January, 1777, to the 1st of January, 1784, and of fifteen per cent. from the 1st of January, 1784, to the 1st of January, 1791, on the ad valorem value of all silk produced in America and imported into Great Britain in vessels regularly navigated by law, was substituted in its place.

The inhabitants of Ebenezer resumed the culture, which with them had long been dormant, and its revival at that time was principally owing to the influence of a very worthy man and magistrate, (Mr. Wertsch) who, sanguine himself of ultimate success, had imparted to the Germans a portion of his own enthusiasm.

In 1770, they shipped two hundred and ninety-one pounds of raw silk, the result of their own industry; and as the filature at Savannah was discontinued in 1771, the Earl of Hillsborough, ever anxious to advance the produce, warmly commended the zeal of the Saltzburgers, and directed President Habersham to distribute "the basins and reels that were left in the public filature to such persons as Mr. Wertsch shall recommend to be proper objects of that bounty;" and in the same letter he promised that he would endeavor to procure for them this year "a small sum from Parliament, to be laid out in purchase of utensils for the assistance of the poor sort of people in your province." This promise he redeemed.

So popular had the silk business become at Ebenezer that Mr. Habersham, in a letter dated the 30th of March, 1772, says "some persons in al-

most every family there understand its process from the beginning to the end." In 1771, the Germans sent four hundred and thirty-eight pounds of raw silk to England, and in 1772 four hundred and eighty-five pounds, all of their own raising. They made their own reels, which were so much esteemed that one was sent to England as a model, and another taken to the East Indies by Pickering Robinson. The operations at Savannah were now totally discontinued, though Mr. Ottolenghe still styled himself "superintendent of the silk culture in Georgia," and, in consideration of his long and faithful service in that office, received an annuity of £100.

In a message of Sir James Wright to the Commons House of Assembly, 19th of January, 1774, he says: "The filature buildings seem to be going to decay and ruin; may it not, therefore, be expedient to consider what other service or use they may be put to?" And the assembly answered: "We shall not fail to consider how it may be expedient to apply the filature to some public use." And henceforth it was used as an assembly or ball-room, a place where societies held their meetings, and where Divine service was occasionally conducted. More recently it was converted into a dwelling house, and was thus appropriated at the time of its destruction by fire on the afternoon of March 25, 1839.

Thus ended the grand project for raising silk in the province of Georgia; for though some few individuals, together with the people of Ebenezer, continued to raise small quantities, yet, as a branch of general culture, it has never been resuscitated. The last parcel brought to Savannah was in 1790, when over two hundred pounds were purchased for exportation at from 8*s.* to 26*s.* per pound.

On reviewing the causes which led to the suspension of this business after so many exertions and such vast expense, which, it must be remembered, the profits of the culture never reimbursed, we find, first, the unfriendliness of the climate, which, notwithstanding its boasted excellence, interfered materially with its success. Governor Wright frequently speaks of its deleterious influence, and the fluctuations in the various seasons evidenced, to demonstration, that the interior was better adapted to the agricultural part of the business than the exposed and variable seaboard. Mr. Habersham, in a letter to the Earl of Hillsborough, dated Savannah, 24th of April, 1772, thus expresses himself on this point: "Upwards of twenty years ago, if my memory does not fail me, Samuel Lloyd, esq., of London, who was one of the late trustees for establishing this colony, and was fourteen years in Italy, and very largely concerned in the silk business, wrote to me that the best silk was produced at a distance from the seacoast, owing, I suppose, to the richness of the soil, which made the mulberry leaf more glutinous, nutritive, and healthy to the silk worm; also to their not being obnoxious to musquitoes and sand flies, and probably, likewise, to the weather being more equal and less liable to sudden transition from heat to cold; and on a conversation this day with Mr. Barnard, of Augusta, he assures me that, from two years' experience in raising cocoons there, he lost none from sickness, which frequently destroys two thirds of the worms here; and he further says that Mr. Ottolenghe told him that the silk reeled from the Augusta cocoons 'made the strongest and most wiry thread of any raised in these parts.'"

Second, the expensiveness of living and the dearness of labor, which was as high as 1*s.* 8*d.* to 2*s.* per day, whereas 2*d.* or 3*d.* was the usual price paid the peasant in silk growing countries. Governor Wright, in a let-

ter to the Earl of Hillsborough, frankly told him that, "till these provinces become more populous and labor cheaper, I apprehend silk will not be a commodity, or an article of any considerable amount."

Third, the great reduction of the bounty, which, being the stimulus to exertion, ceased to operate as an incentive, when from 3*s.* 3*d.* it fell to 1*s.* 3*d.*, and finally to a mere premium on the general quantity imported. The poor could not subsist on these prices, and the rich could employ their lands to much better advantage than in cultivating an article which would not repay the expenses of labor; and, lastly, the increasing attention bestowed on rice and cotton sealed the fate of the silk culture, and the planters soon learned to consider the latter of no importance, in comparison to the large and lucrative crops yielded by those more staple commodities. Other reasons might be mentioned, but these sufficiently account for its decline there, and its total neglect even to the present day. During the morus multicaulis epidemic, which spread over our country in 1838, Savannah, it is true, did not escape, and for a time the fever raged with much violence; but the febrile action soon subsided, leaving no permanent benefit, and only a few fields of waving foliage as a deciduous memento of this frenzied excitement.

That silk can be produced in Georgia equal to any in the world, does not admit of a doubt; but whether it will ever be resumed, and when, are among the unknown events of the future.

From the New York Farmer and Mechanic.

In the New York Farmers' Club, November 18, 1845.

SILK.

Mr. Van Epps.—The subject of bounties on silk ought now to be taken up. Our State bounty for five years will expire next June. That bounty is 15 cts. a pound for cocoons, and 50 cts. a pound for reeled silk, the produce of this State. A bushel of cocoons weighs 10 to 12 pounds. This bounty induced many persons to raise silk. If the bounty ceases they will probably quit the raising of it. Some gentlemen, I know, await the action of the State before they engage their capital in the business. Massachusetts and New York are, I believe, the only States of this Union that give such bounties. Other States have repealed their bounty acts. The business cannot yet continue without bounty. We can raise silk, but the first attempts must be fostered and patronised, or it must fail; and, besides, frost has recently almost totally killed our multicaulis trees, and we have to wait the growth of hardier kinds, adapted more to such severe frost as sometimes occurs. Confidence in the ultimate success of the silk staple in America is unabated. I move for a committee of three to prepare a memorial on the subject to the legislature.

Dr. Underhill.—Was the Broussa mulberry killed?

Mr. Wakeman.—No, sir. Broussa survives all frosts: we must have that question brought before this club for particular investigation.

Mr. Fleet.—This is the most important question that has been before this club for some time. The bounties on silk are of too short a duration. The public has not that confidence in their continuance which is abso-

lutely necessary to induce any prudent man to establish his mulberry trees, and his accommodations for the worm, &c. I am sanguine that bounties continued ten or fifteen years would secure the silk culture. I second the motion for a committee. Motion carried unanimously.

Mr. Kemble.—How long shall we ask for bounty? Ohio has none; Connecticut has none; and they produce the most silk. The bounty is equal to the cost of production. The legislature will not give you ten years! The bounty might become very great. Let the committee report their memorial at the next club.

Mr. Meigs.—If the State should pay $5,000,000 for bounty on silk at 50 cts. a pound, and the silk raised should be worth what it now is, and doubtless always will be, $5 a pound, then *the benefit to the State* would of course be about forty-five millions of dollars.

Mr. Fleet.—The memorial drawn by the committee should be reported to the next meeting of the club.

Seconded by Mr. Kemble.

Dr. Underhill.—It is admitted that 50 cts. a pound for the silk pays the cost of raising.

Mr. Van Epps.—Two dollars will pay for the trouble of raising a pound, after the establishment is ready for it.

Mr. Fleet.—To avoid injurious prejudices, I should prefer a sliding scale of bounties.

Mr. Meigs.—The infancy of a great staple may be justly compared with that of an animal. You must nurture and sustain the infant, or you will never have the strong and powerful adult. That is the true nature of bounties.

Mr. Kemble.—I am for prudence in our measures: a bounty is a help only; government ought not to do the whole. How does Ohio manage it?

Dr. Underhill.—The damage done by recent frosts to the mulberry trees will not be repaired soon; a bounty for five years would not more than repair that damage. Millions of the trees are destroyed, especially where they stood in loose soils. I think that the bounty should be continued for five years, and then reduced a quarter or a half for five more.

This club cannot take up a more interesting subject than that of the kind of mulberry best suited to our climate. Broussa stands our frosts perfectly. Italian white is also said to stand it; but multicaulis has been almost annihilated. The fatal blow was struck the winter before last, when frost entered the ground here three or four feet deep.

Mr. Van Epps.—Two dollars pay only for the labor of raising a pound of silk. The business in Ohio ought not to give the tone to the public. A hundred years ago the silk business was struggling in this country. Had it been duly encouraged, it would have been long ago a great source of national wealth.

Mr. Wakeman.—The silk raised by us has probably, when all costs are considered, really cost us about five dollars a pound. Much time and great ingenuity are requisite to establish the silk business in America. Our first attempts at making cotton cloths were full of difficulties. At first we got 25 cents a yard, then 12, (*all said we must fail,*) then 6; and yet at 6 cents a yard, after numerous expenses in money, and great ingenuity in machinery, cotton cloth is an *American article* at that very low price. We are making $40,000,000 of cotton fabrics; we can do so with silk. But the most important business of reeling silk must be yet established. Some kinds

of India silk, for want of proper reeling, are worth $2 50. French of no better quality in the cocoon, yet by good reeling, brings $5 a pound. In Ohio, silk is reeled worth it now, on a small scale.

As to multicaulis, the records of this Institute will show that years ago it was declared here that multicaulis would fail, and it has failed. We believe that *Broussa* will stand—it has been examined by us; we doubt not its physical adaptation to our northern climate.

The motion that the committee do report the memorial to the next meeting of the club was *unanimously adopted.*

The *chairman* appointed on that committee Messrs. Van Epps, Skinner, and Meigs.

From the New York Farmer and Mechanic.

SILK CULTURE.

Last stroll of the season among the mulberry patches, cocooneries, and eggeries of Northampton.

Northampton, *November* 10, 1845.

Dear Sir: You have been furnished with several strolls among the mulberry patches, cocooneries, and eggeries in Northampton, with an allusion to experiments in contemplation to show the practicability, and, if possible, the utility of late feeding, despite the use of old, crude, spotted, or frost-bitten foliage; and, if successful, the worms would go up, by or before the *memorable powder plot* of November 5th; at which time, instead of *going up*, they stayed *down*, and the finale was a total destruction of the whole family, without the intervention of gunpowder or nitrous explosion.

Having ever been of the opinion that late raised cocoons were of little or no value, the experiment was made, to show, practically, that there can be no use or profit in late feeding, and to establish the fact that *our early crop* is worth more than all the after crops when the foliage becomes crude and indigestible.

A French writer has produced evidence that 100 lbs. of seedling foliage will make as much silk as nearly double that quantity of old foliage.

The question may be asked, how early ought eggs to be brought out?

Answer.—Soon as the mulberry begins to develope its foliage.

Another question: suppose the early foliage should be cut off by frost?

Answer.—Then shift the worms to mulberry paper, or use foliage which had been dried for the purpose; pulverize, moisten, and sprinkle with a little wheat flour or rice flour, (which is preferable,) and the worms may be sustained until new foilage appears. This has been successfully tried.

An order for Canton trees or cuttings, and peanut eggs, has been received a few days since from Lima, Peru, S. A., and means to preserve the worms, should they hatch on the passage, for which purpose mulberry paper and dry mulberry foliage will be forwarded. Eggs have been forwarded to the Sandwich islands which did not hatch until they had arrived at the place of destination, five months' passage or more, where was plenty of foliage. Our motive for ordering northern eggs for Lima is, that they are considered peculiarly adapted to a warm climate, in preference to the product of that climate.

President Stiles, in his Silk Journal, advocated and recommended frequent change of stock.

The eggs which were sent to the Sandwich islands were of the peanut variety, 3,000 of which, or even less, if well fed, would give one pound of silk; but, when crossed with the native breed, required between 5,000 and 6,000 to make a pound of silk, and soon the mixture were like the native, and the same lot of the native eggs became very irregular in the time of hatching—some in ten days after being laid, others up to thirty, sixty, ninety, and others even to six months. This irregularity has been very discouraging. Such, also, has been the experience in the West India islands, as by recent intelligence. The only apparent remedy is the *frequent* or *annual* supply of northern American eggs.

Eggs sent from here to the south have done well; but when received from the south, the reverse, so far as my experience has extended, from the beginning to the end of the *stroll!*

A. C. Van Epps, Esq.

Remarks.—It was stated in this paper, a few months since, that northern eggs sent to the south generally did better than those saved there, or southern eggs sent here. This statement has been doubted and contradicted, but we have made diligent inquiry, and have yet to learn *an instance* where eggs sent south have failed, where the failure could not be traced directly to some other cause than any injury in the eggs consequent upon a change of climate. We have sent several pounds, during the last year, to the *extreme* south, and they have done *well*. They may be safely sent any part of the season, and with great advantage to the grower.

A. C. VAN EPPS.

From the New York Farmer and Mechanic.

IN THE NEW YORK FARMERS' CLUB.

* * * * * * * * *

Mr. Meigs, from the committee to whom was referred the subject of a memorial to the legislature for renewal of the bounty on the culture of silk, read the following report:

To the honorable legislature of the State of New York:

The American Institute respectfully comes before you in favor of the public, to ask for a renewal of the bounty on the production of silk in this State. The great natural staple of our land yet requires the paternal care of the State. The existing bounty, which expires in June next, has been the means of causing some attention to that important product, but competition of foreign nations, long habituated to that very delicate and very valuable product, renders, in our opinion, a still further help necessary on the part of government, to carry it from its present infant condition to maturity.

The legislature is perfectly aware that silk has long been, and will undoubtedly forever be, almost an article of necessity. Every citizen uses it, and must continue to do so; for it is admitted everywhere to be one of the most beautiful and useful materials for the dress of our race that can be found. As a thread only, it has no equal; and for beauty as a garment, no superior. And it is also now ascertained as a fact, that the United States has a climate

better adapted than any other on the globe for the production of it. It has cost our country a great many millions of dollars to buy it from the old world; and we believe it to be high time for us to make it, not only for our own immense consumption, but to try to make it for exportation, and thus cause other nations to repay us the tribute for silk which we, for generations past, have paid to them.

Difficulties besides competition have attended this new staple of our country. The experiments tried in this new business have some of them failed. Certainly, mulberry trees which came as highly recommended as the multicaulis have proved unable to bear our winters. The multicaulis has failed, to the very great damage of thousands of our patriotic citizens, who had ventured their fortunes in its trial. But it is now well known that other kinds of mulberry trees are capable of standing unhurt our hardest winters. The Broussa is one of them. We would therefore persevere, by all means; and we believe that upon further examination our State government will see the propriety of continuing its bounty for some years to come.

Upon much consideration, we have arrived at the conclusion that, if the present bounty should be continued for three years, and then be decreased ten per cent. per annum until exhausted, the production of silk in our State will be so firmly established as no longer to require the parental care of government.

If the amounts paid for such bounties should, as we hope they may, become large, it will be a source of high satisfaction to know that our citizens are enriching themselves and the State by the amount of silk produced.

And we beg leave to say that bounties for the destruction of wolves and panthers cannot wisely be considered more advantageous to the State than the production of a new staple of commerce, and lasting value, like that of silk.

Your honorable body will, in its wisdom and patriotism, supply those reasons which we may have omitted. Your memorialists therefore submit with perfect confidence and respect, for decision, this petition, which was unanimously adopted, and ordered for signatures and presentation to the legislature.

On the subject of the best mulberry tree for our climate, although the multicaulis has failed in some situations, yet the Broussa, the Italian white mulberry, and the Alpine, stand our climate well.

Mr. Van Epps.—I have used the multicaulis, the real Chinese mulberry; all that we have of this tree are descended from two plants brought from the Philippine islands. There is no failure from cold on the high lands of our country, but, for the last two years, those planted in our low lands have suffered greatly from severe frost. The stem of the multicaulis is apt to be destroyed by hard frost, but the roots are usually not hurt, and the young shoots the following year bear well. The best method is to cut off the stems with their leaves and give to the worms. They may be cut twice or thrice, and the leaves on the upper end of the stem are not so good for the worms. I cut off the upper six or eight inches; those leaves are watery; they will do to feed the young worms. Multicaulis is now almost the only mulberry used in the south, where it succeeds on low land and high land. Multicaulis has rapid growth, and gives per acre four or five times more food for worms than any other mulberry that I know of except the Broussa. I would, in the fall of the year, cut my stems down to the ground and turn a furrow over the roots. The white grafted mulberry is fine. It is suc-

cessfully done, and the result may be examined at No. 337 Broadway, in this city. A gentleman from Albany proposes to plant thirty acres of the Italian white mulberry. The silk-worm is not fond of our American red mulberry leaf.

Mr. Wakeman.—That has been tested by the Institute.

Chairman.—The morus oregana (the Oregon mulberry) is good—has large leaves; a specimen of it is possessed (I think) now by Alexander Walsh, of Lansingburgh. We ought to carefully examine that mulberry.

Mr. Van Epps.—Mr. Clark, of Philadelphia, has published the best treatise on American silk. I refer members to it for information.

Mr. Wakeman.—On the 19th June, 1828, on suggestion of the late Dr. Felix Pascalis, the American Institute commenced the undertaking to supply our country with mulberry trees. A large amount of the best seed was imported from France by the American Institute. Dr. Pascalis constantly recommended the obtaining a plentiful supply of the leaves before we undertook to employ the silk-worm. In that same year the first multicaulis was imported by Dr. Pascalis, as chairman of the silk committee of the Institute, and shown at the fair. When introduced to public notice, it was not supposed by many, as well as by myself, to be sufficiently hardy to endure our cold weather; and so has it proved generally. We must have a tree better fitted for our climate. It will not answer to have our silk-growers liable to the severe disappointments from killing frosts. They will be discouraged. Multicaulis may do for our southern States; but here we must have the Broussa. We obtained this kind from Mr. David Ruggles, of Newburgh, in 1837, who obtained it from Charles Rhind, esq., one of the commissioners by whom the late treaty was concluded between the United States and the Sublime Porte. Broussa is in the same latitude as New York; is situated at the foot of mount Olympus, the summit of which is crowned with perpetual snow. He believed that it was more hardy than either the morus multicaulis or the Italian mulberry. Mr. Rhind shipped to Mr. Ruggles several hundred of the young Broussa trees, all which perished on the voyage. In 1832 Mr. Rhind obtained seeds of that year's growth, and gave them to Mr. Ruggles, who planted them, and in 1837 he had 20,000 trees. It has proved able to bear our winters. Its leaf is as large as that of multicaulis, but thicker—more pulpy. It has stood side by side with multicaulis unhurt, while that was killed by frost.

Mr. Hyde.—I tried the white Italian mulberry in Missouri, in 1836. I planted them in a garden of rich soil; the weeds overran most of them. Such as escaped I transplanted, and now they are as large as common apple trees; and I planted slips from them, which have grown successfully. Cattle are very fond of the leaves, and some of my mulberry trees were cut down by them, but their new shoots are vigorous. I believe there is no multicaulis now living in Missouri more than ten feet high. The cold of our winters invariably kills the stalk down to the ground every year. As to the white mulberry, I have never yet seen the little ends of its branches hurt by frost. But I still think that the northern part of Massachusetts is too cold for the white mulberry. The red mulberry grows all over the west; the white grows well on land of inferior fertility. I tried the multicaulis and the white mulberry side by side.

Chairman.—The plan proposed by Mr. Van Epps is good, to cut down the stems annually and loose up the roots with the furrow of the plough.

Mr. Hyde.—We ought not to depend on the annual shoots for our supply of leaves.

Chairman.—The multicaulis tree never does attain a large size.

Mr. Hyde.—When the white mulberry tree is cut off to the root, it branches out well afterwards.

Mr. Wakeman.—We must place our reliance only upon such mulberry trees as are capable of standing all the vicissitudes of our climate unhurt. We must have a permanent tree. All the other arrangements mentioned are somewhat troublesome, and therefore very liable to neglect. The Broussa is undoubtedly our best tree. Mr. Ruggles thought that the greater solidity of the leaf rendered it fully equal to multicaulis; that the silk-worms would leave the latter to feed upon the former. I had in my garden a Broussa which grew rapidly; it was readily propagated by slips. I move for a committee to inquire after and collect the Broussa. Carried.

The *chairman* appointed on that committee Messrs. Dr. Underhill, Wakeman, Meigs, and Van Epps.

Chairman.—Let the committee inquire of Mr. Walsh for the morus oregana—it is very valuable.

Mr. Van Epps.—We are almost destitute of mulberry, and it is of the first importance to the silk business that we should have a permanent supply.

AN ACT TO ENCOURAGE THE CULTURE OF SILK.

Sec. 1. *Be it enacted by the Senate and House of Representatives of the State of Louisiana in general assembly convened,* That the treasurer of the State shall pay, out of any money in the treasury not otherwise appropriated, fifteen cents for each and every pound of silk cocoons hereafter produced within this State, and the sum of fifty cents for each and every pound of raw silk reeled in this State from cocoons raised within the State, as a premium for raising such cocoons, or reeling such silk.

Sec. 2. *Be it further enacted, &c.,* That before any person shall be entitled to receive such premiums, he shall prove to the satisfaction of the parish judge of the parish in which said persons reside, or of the district judge if no parish judge should be in office, that the cocoons were raised, or the silk was reeled, by him, or by other persons under his authority, within his said parish.

Sec. 3. *Be it further enacted, &c.,* That the parish judge, or district judge, as the case may be, may examine such persons on oath or otherwise; and he shall be fully satisfied that such persons did raise the cocoons, and did reel within said parish such raw silk, from cocoons reared within this State. The said parish judge shall thereupon give such persons a certificate of the facts so proved to him, that neither the said cocoons nor reeled silk, nor any part thereof, has ever been presented or offered before for the purpose of obtaining a premium thereon as allowed by this present act, which certificate the treasurer of the State shall receive and pay.

Sec. 4. *Be it further enacted, &c.,* That a parish judge, or district judge, as the case may be, shall be entitled to receive, for every certificate given by him by virtue of this act, twenty-five cents, to be paid by the person receiving the certificate.

Sec. 5. *Be it further enacted, &c.*, That any person violating the provisions of this act, by attempting to procure certificates more than once, or allowing the use of the cocoons or raw silk to any person else, for the purpose of procuring another certificate, one having been granted, shall be deemed guilty of swindling, and on conviction thereof, as in other cases of swindling, under the criminal laws of this State, shall undergo confinement for swindling; and the person applying for a certificate, knowing one had already been granted to another person for the same cocoons, or raw silk, shall be likewise deemed guilty of swindling, and punished, on conviction, as the criminal laws of the State prescribe for perjury.

Sec. 6. *And be it further enacted, &c.*, That this act shall be in force five years.

A. BOUDOUSQUIE,
Speaker of the House of Representatives.
FELIX GARCIA,
President of the Senate.

Approved March 10th, 1845.

A. MOUTON,
Governor of the State of Louisiana.

From the New York Farmer and Mechanic.

SILK CULTURE.

A number of valuable communications have been received since the last number was issued, (several of which are of great interest,) from gentlemen at the *extreme south.* They show an increasing attention to the culture of silk. The only obstacle named in any of them is the "want of a market," and applications have been made by growers in Georgia and Tennessee to send their cocoons to our *filature.* The following, from Thomas Douglas, esq., of Macavriz, East Florida, to the Hon. D. Levy, will be read with much interest. We are happy in being able to inform our friends that branch filatures will probably be established during the ensuing season in Georgia and Tennessee. Communications from Dr. D. Stebbins, of Mass., and Judge Ernest, of Georgia, Mr. Massey, of Alexandria, and others, will appear in due time.

In speaking of the Farmers and Gardeners' Convention, and Silk Growers' Convention, in previous articles, we referred to those held under the auspices of the American Institute, October last.

A. C. VAN EPPS.

Macavriz, *East Florida.*

Dear Sir: Although my experiments in the silk culture may be of little value, yet, added to the general stock which is now being gathered up by those who feel a solicitude for the success of this branch of agriculture, they may be of some service, especially to our Territory, in all that concerns which you take so deep an interest. I therefore proceed with pleasure to comply with a request you made of me before you left for Washington, to give you some information on the subject. The feeding of silk-worms began to attract attention in this region in 1838. Few, however, engaged in it. Mrs. D. that year fed a small number by way of amusement, which succeeded so well that we were induced to continue it. In 1839 we fed

about ten thousand worms, and although (from necessity) we kept them in a small, close, and badly ventilated room, they were throughout perfectly healthy, wound off well, and made very fine cocoons, weighing about 275 to the pound. Encouraged by this, and believing that the culture might be carried on successfully here, become a valuable branch of our agriculture, and bring into requisition a large portion of our fine timbered lands, I determined to proceed with it; and in the spring of 1840 commenced the erection of a building suited to the purpose, which I have since finished. That spring I had a large crop (or family, as the French writers would perhaps more correctly call it) hatch out, but, owing to the want of room for them, made only about 40 bushels of cocoons. This crop wound off in April. In the succeeding month of May I brought out another small crop, from some choice eggs sent me from the north, which turned out well. In June and July, I brought out another crop of about five thousand worms; these were the second crop of the small white two-crop worm, a very hardy and valuable variety; and although we fed them in the attic story of my new cocoonery, amidst the noise and dust occasioned by the carpenters and masons who were engaged in finishing it at the time, they were exceedingly healthy, and wound off in the month of August very handsomely. In 1841 we fed two crops of about 150,000 each; the first in March and April, and the latter, which consisted of the two-crop worm, in May and June, and made about one hundred bushels of cocoons. There being no ice-house in this neighborhood, we could not avail ourselves of the advantage of giving our eggs what is termed a "*temporary winter*." so as to cause them to hatch again that season, and were therefore compelled to forego further feeding until the ensuing spring; but during the month of March we brought out a crop of about 300,000, which worked off very handsomely in April and May, from which we made about seventy bushels of cocoons. Being too much engaged with professional pursuits to go north to procure reelers, or the necessary apparatus for reeling, and having no knowledge of that matter ourselves, except what we have derived from our experiments, and little time to devote to it, we have most of our cocoons, say about 200 bushels, yet on hand. We have, however, with such apparatus as we could procure here, which is by no means the best, reeled off enough to ascertain that our cocoons, which I think would not suffer by a comparison with any made elsewhere, will make very fine, strong, and excellent silk. To satisfy you more fully upon this point, I herewith enclose you a small sample reeled in my family, and saved a large quantity of eggs; but notwithstanding a large portion of the latter were of the small white two-crop worm above mentioned, they did not hatch out a second time—a circumstance for which I am unable to assign any reason, unless it was owing to a long continuance of hot dry weather, which some writers on the subject say will cause that result. An ice-house having been established in St. Augustine, I about the middle of July placed a small quantity of my eggs, assorted, in it, in order to test the fact whether giving them a "*temporary winter*" would cause them to hatch, and, being very much pressed with business, paid no further attention to them until about the middle of September, when I took them out and spread them on a shelf in my cocoonery, and in a few days they commenced hatching, and we fed them through the months of October and November; they also were healthy, and wound off well.

I used no artificial heat, and am satisfied, from my own experience, that

we can always feed here eight months in the year without it, and in favorable seasons nine months, during which time we can make four crops, provided we can manage our eggs so as to cause them to hatch out when we wish them to do so; and I see no reason why we may not. I am aware that different opinions are entertained on this subject; it is contended by some that retarding the hatching in the manner I have mentioned must necessarily injure the constitution of the worm. I do not think so. Providence seems in every other respect to have adapted it to the use of man; its want of locomotion is a remarkable instance of that adaptation. If it crawled about like other worms, we could do nothing with it; and I believe that it is also adapted to that use in the particular that I have mentioned; an opinion to which I am led by observations and experience. This opinion I know is at variance with that of some writers, and amongst others Mr. G. B. Smith, of Baltimore, whose opinions upon all questions connected with the silk culture are entitled to great weight. He says, "that the silk worm, when left to itself, exposed to the ordinary atmosphere, hatches out in the spring, exactly at the time the mulberry leaves open; that it is, therefore, '*an annual insect*,' and requires exactly twelve months to pass through the various stages of it existence;" that if, for example, a silk-worm is hatched on the first of May, 1840, the eggs that it would produce would naturally hatch on the first day of May, 1841. In this I think he is mistaken; and, with all due deference, there seems to me to be an inaccuracy between his premises, which are correct, and his conclusion, unless the mulberry leaves come out always exactly at the same period of the year, which is by no means the case in this latitude. I never laid by any eggs from silk-worms that hatched earlier than about the 10th of February, until last year; yet I have almost every winter had worms hatch out whenever the temperature of the atmosphere was as high as 70°, in the following December and January, which is often the case here. Again, in consequence of cool weather at the same period of the year when the worms were hatched, from which they were produced, the hatching has been retarded; indeed, that is the case now. Many of the worms that produced the eggs I now have on hand were hatched before the 10th of February of last year; yet they have not hatched—owing, doubtless, to a backward spring, and by keeping my eggs in a cool place. I have also retarded their hatching beyond the period of the year at which the worms that produced them were hatched, without any prejudicial effect, so far as I could discover, upon the worm. But the Persians, it is said, possess a variety which produces eight successive crops in the year; and if I am not wrong in relation to the theory above mentioned, it will be a desideratum to introduce this species in Florida, where it will find a congenial climate. I observe that at a silk convention held in the fall of 1843, at Northampton, Massachusetts, Mr. Samuel Whitmarsh, whose experience in the silk culture is well known, stated that he was satisfied that but one crop could be made in the year in New England; and the principal reason assigned by him why more could not be raised, was, that the mulberry tree would not afford suitable food a longer period than was necessary for one crop. I use the leaf of the morus multicaulis, and that affords good forage for silk-worms here *at least eight months*, and sometimes nine, and even ten months in the year.

The advantage that I anticipated for Florida from the silk culture, in relation to our pine barren lands, (as they are called,) will doubtless be re-

alized; for although the trees raised upon those lands do not produce so large leaves as those raised on the rich hammock lands, yet they afford a better food, and the silk made by the worms fed upon them is stronger and of a finer texture. By the by, I am happy to learn that the experiment of cultivating sugar upon the pine lands in the interior also succeeds well. The cane raised upon them, although not so large as those grown upon the swamp lands, contains much more saccharine matter to the gallon. There is a great saving of labor, therefore, in handling and transporting it to the mill, and in grinding it. The same result as to silk culture upon the pine lands has attended the effort in Georgia. A writer in the last "Georgian," speaking of the experiments made there, says: "that pine lands are suitable for the production of the best qualities of silk." I now consider it as determined, and the fact to be of great importance to the neighboring counties, and especially to Savannah. If the pine country in our rear, which has been regarded as little more than waste lands, can be made productive, and subsist a dense population, what would now seem the most visionary calculations of such a change to Savannah and the country at large would *fall short* of the *reality*. But I venture to predict such a change, and that whoever may live to see thirty years hence will see "*lower country Georgia silk*" quoted in the prices current of Liverpool and Havre. I certainly agree with this writer; and what will be true of Georgia will also be true of Florida; and those who live at that day will also see "Florida silk" quoted in the same prices current; but while East Florida may compete with Georgia and States further north in the cultivation of silk, and that, too, with superior advantages, she will produce several staples in the cultivation of which they cannot compete with her, amongst the more important of which will be that of sugar. And now that the din of war has ceased, and the overflowing scourge that has so long devastated this fair portion of Florida has passed by, we may hope soon to see the country settled by an industrious, intelligent, and enterprising people. There is no portion of our country (or perhaps any other) that offers greater inducements to the emigration of that class of people than East Florida.

I have visited almost every portion of the United States, and spent many years in the noble valley of the Mississippi, (which might with propriety be called the "garden of the world,") while the country there was new, and I can say with confidence that I have seen no country where *industry*, *enterprise*, and *economy* usually met with a better reward than in East Florida. A catalogue of the crops suited to the soil and climate, and of the spontaneous vegetable productions, would embrace almost everything found at the north, with the addition of many others of exceeding value, not found in colder latitudes. Amongst the last are the orange, and almost every other tropical fruit; and as to the healthiness of the climate, it is too well established to require any comment. Some portions of the army, to be sure, suffered much from disease during the late Indian hostilities; but I am told that an examination of its statistics will show that it suffered less from that cause in Florida, in proportion to numbers, than it did in the northern and northwestern frontier during the last war with England.

The temperature is a pleasant medium, between the extremes of heat and cold. By a register of the weather, kept for two years at Charlotte Harbor, the mercury never stood but once as high as 90°, nor sunk but once as low as 50°. Further north the extremes are somewhat greater; but at St. Augustine the mercury seldom rises above 90°, or falls below 30°. But, to use the language

of a writer in a late number of that valuable work, "The Journal of the American Institute," there are other considerations of high import to the enterprising agriculturist, in favor of locating in East Florida. It has been satisfactorily proved by the late indefatigable and much to be lamented Doctor Perrine, that almost any article grown between the tropics will flourish as well, and in some cases better than in their native soil. And the entire catalogue of spices and other articles, for which we now make long and perilous voyages to the opposite side of the globe, often to unhealthy climates, and always incurring vast expense, can be grown in our own Territory, and furnished at a cheaper rate and in better order than those obtained of the half-civilized Asiatic islanders. In addition to all which, cattle, horses, and hogs may be raised in any numbers upon our fine grazing lands, with little or no attention from man. Our rivers and lakes abound with fish of the greatest variety and best quality; our wood-lands with the most valuable lumber. And it requires not, as in colder regions, the labor of one half of the year to provide for the other. When all these things are considered, in connexion with the fact that East Florida already produces three of the most valuable staples in the world—Sea island cotton, rice, and sugar—it will, I think, be readily acknowledged that few new countries, if any other, have ever offered advantages to emigrants superior to those now offered by East Florida. But I crave your pardon: you only asked me some account of my operations in the silk culture, and I have spun out what I fear will be a tedious article.

I am, sir, yours, &c.,

THOMAS DOUGLAS.

Hon. D. Levy.

From the Dollar Farmer.

SILK CULTURE.

Since the explosion of the morus multicaulis speculation, the silk business in Kentucky has not advanced with very rapid strides. Some of those persons who took hold of the business as a business, and investigated the subject properly, are now, by their careful, slow, and patient progress, demonstrating that the pursuit is both safe and profitable, and easily connected with other farming business.

Mr. John Cain, of Meade county, called on us the other day and made a statement of his experience in silk culture, the results of which are gratifying. He states, that on the 20th of April last he commenced feeding twenty thousand worms upon the foliage of the white or Italian mulberry, and, three weeks after, he commenced feeding upon the multicaulis. About half the worms were destroyed by the late frosts, and but two bushels of cocoons was the result, making two pounds of beautiful reeled silk. On the 20th of May he commenced feeding a second crop of twenty-five thousand worms entirely on multicaulis, and lost one third of them by mice and birds. Four bushels of cocoons was the result, three and a half bushels of which produced three and a half pounds of silk, and the remainder ten ounces of eggs. The third crop of twelve thousand worms he commenced feeding on the 26th of June, one-fourth of which died of the muscodine, a disease which he checked effectually by sprinkling cold water upon them. This remedy

deserves to be generally known. The result of this crop was two and a half bushels of cocoons, two bushels of which produced two and a quarter pounds of reeled silk—a better product, it will be seen, than the first crop. He fed the foliage of only one-quarter of an acre of trees, planted in 1840 and 1841, and he did all the work himself alone. He gives the pecuniary result as follows:

7¾ pounds reeled silk, sold at $5 - - - -	$38 75
4 ounces eggs, at $12 (market price) - - -	48 00
Total - - - - - -	86 75

Mr. Cain states, that besides attending to the silk-worms he attended to his other farming business about as well as his neighbors, and raised, among other things, twenty acres of oats, which produced three hundred bushels, worth at least fifteen cents per bushel; making forty-five dollars. The twenty acres of oats thus produced forty-one dollars and seventy-five cents less than the half acre of mulberries. He further says that it would take him four days or more with his team to haul his crop of oats to market, while he could take his crop of silk, of greater value, under his arm, without difficulty, and walk with it. The twenty acres devoted to oats constituted the very best portion of his farm, and the half acre devoted to mulberries is the very poorest. Mr. C. says that the season has been very unfavorable for the silk business, and that generally a better result may be relied upon. Mr. Cain used a log building, thatched, but he thinks that open sheds are preferable, and he is now erecting one seventy feet long for next season's operations. Nothing is so injurious to the worms as confined air. His worms have always done as well on the Italian mulberry as on the multicaulis. He cuts the twigs, but does not pluck the leaves, as by this means the tree is kept down to its convenient stature and form, sustains no injury, and a much larger amount of foliage can be gathered in a given time; thinks it better to gather them after the dew begins to fall; and thinks that his success depends very materially on the fact that he has used eggs which produced the Chinese *peanut cocoons*. Though he has saved no more eggs than he wants for his own use next year, (as he means to feed four acres,) he is willing to part with a few thousand eggs, a thousand in a place, for the purpose of aiding in the introduction of an improved stock in the country. They can now be forwarded by mail, and we are authorized to say that orders addressed to him, post paid, at Brandenburg, Kentucky, enclosing twenty cents for a thousand eggs, will be attended to.

Mr. C. says he has lost many eggs by keeping them in ice, but has been entirely successful in keeping them under ground in a saltpetre cave which he has. It would perhaps do as well to have them in a glass jar, well sealed with wax, so as entirely to exclude moisture, and placed in an excavation some six or eight feet deep in the bottom of an ordinary cellar, where water can be excluded, or even suspended in a deep well.

If we add that Mr. C. has found it advantageous to change his worms occasionally, when feeding, from one place to another, we have probably given all that is at all peculiar in his management, and all the principal points which can be of value to those who have read the popular treatises upon the subject.

Of course no sensible man would propose to make the silk business take

the place of all other branches of husbandry. But it no doubt deserves a place among other branches. It is simple, and can be carried on successfully by women, children, and the aged and crippled. But little land is required, and the poorest appears to be as well adapted to this culture as the best. A man having a few acres of poor worn-out land in our mountain counties, with a large family of children, could not do better than to occupy a portion of his soil with the mulberry. There is a certain market for all his cocoons and reeled silk in this city and elsewhere, and prices are far more uniform and fixed than those of almost any other article of produce. There is a demand at the silk factory in this city for more than can be produced for some time to come in this State. Raw silk is now imported from Europe in large quantities, to be manufactured in this country. Besides, the imports of manufactured silk amount to several millions. There is no danger that the business will be overdone. No teams are required, and there is no branch of farming that can be carried on with so little capital. Cuttings and roots of both the Italian mulberry and the multicaulis can now be procured for nothing, or next to nothing, and they can be cultivated and propagated as simply and certainly as the currant bush. It may be added that the perforated cocoons, not wanted by the manufacturer, can be carded and spun in the family, and constitute an important material of domestic clothing.

From the New York Farmer and Mechanic.

IMPORTANT FROM GEORGIA—SILK WELL-ROPES AND OX-CHAINS.

We regret that the small space necessarily devoted to this department obliges us to withhold from the public many valuable communications from practical silk culturists. We shall endeavor, however, to give the substance of all letters of importance designed for the public eye.

The following extracts are from our friend Judge Ernest, of Macon, Georgia. This gentleman has long been identified with the interests of this enterprise in the southern sections of the Union, and deserves the thanks of all for the perseverance he has manifested in prosecuting the business, in defiance of all opposition; and we can but hope that the fact is beginning to be realized, that silk may be produced at the south with far less expense, and greater profits, than any other crop. As in Georgia, so in every part of our country, people wait for a market, and nothing of importance will be accomplished until measures are matured and carried into operation for purchasing and reeling all the cocoons that can be produced. Since we have been agitating this question, we have been gratified to find our efforts seconded by the proprietors of various agricultural and other publications; and it is our intention to press the measure upon the attention of the public, until it secures the support its importance demands. Judge Ernest says:

"I consider your plan for a filature and market the most important step that has been taken in our country, designed for the advancement of the cause. There was more silk made in Georgia five or six years ago than there is now; and the reason is this: the people could do nothing with their silk (cocoons) after they had made it, and consequently abandoned the business. I have been offered several lots of cocoons for nothing, which

I have refused, because I had more of my own than I could dispose of, unless I have better means for manufacturing. Raw silk accumulated on my hands to such an extent, that I made a *well-rope of silk*, 40 feet long, and an *ox-rope*, bag-strings, &c.; and all because there was no market. I intend to make a favorable impression on the minds of people here in regard to the matter—shall make all the silk I can, turn it into cash, and tell them about it. I have accomplished much in this way already. If I find that there are going to be more cocoons than I can work up into sewing, I shall prepare to reel only. I told an acquaintance yesterday that I should purchase cocoons, and he promised to make all he could. He is a man calculated to carry anything he undertakes into effect. Several others also speak of going into the business. If I can raise a good crop again, I think the question will be settled in this neighborhood, and then it will go like fire in a prairie. I have always been successful, even when I knew less of the business, and had less inducements to prosecute it than I now have. I have 8 or 9 acres of trees, five years old, and room in abundance; so that my future prospects, compared with the past, are extremely flattering. I have done much under very unfavorable circumstances, and from this I infer what may be done under those more favorable. When I commenced the silk culture I knew nothing of the business, and in my isolated condition I had difficulties to encounter that persons in more favorable situations would hardly dream of. In addition to all the difficulties necessarily incident to the business, I was obliged to encounter at every step the opposition of almost every person with whom I was conversant. I am sure I have made the business profitable. We sell our silk to persons who could purchase at Macon, if it were for their interest to do so, and at prices to us satisfactory. Persons residing in Macon frequently purchase silk of us for their own use. I am confident that the United States must some day become one of the greatest silk producing countries in the world. It is impossible for countries where land is so costly as in Europe to compete with us in the production of silk, or anything else that grows out of the ground. It is a long time since I have heard any one express any doubts on these points. But when will you get a *market?* has been the question; a question which I have been unable to answer. If successful in accomplishing present plans, I can furnish a market until the business is too deeply rooted to be easily checked; and this I will certainly do.

"Designing no flattery, sir, allow me to say that I think you deserving the thanks of all the friends of silk culture throughout the entire country. It is very desirable to improve the condition of a solitary individual; but I am confident that you are in a fair way to benefit a great many persons. I do not pass a day without seeing some person whose condition might be improved by the silk culture. We have no bounty in this State, but we can get along without it. If we had a bounty, the business would make more rapid progress; but if it can get along without artificial means, it will always be more healthy and permanent. I have the satisfaction of knowing that although I have heretofore stood alone, or nearly so, the friends of the enterprise are now rapidly multiplying. I know it can be made more profitable than any present pursuit here. I would rather raise silk, than cotton at 20 cents (and it brings only 4 cents) per pound. Our people hang to their old habits, but this cannot be done much longer. If they see me making more money at the silk, they will want to have a hand in it."

From another letter, dated March 11th, we extract the following. It

will be seen from this that Judge E. has this season adopted the system of open feeding, and we predict an increased return for the same amount of labor heretofore bestowed. Indeed, this is certain. Will not Georgians now take hold of the business? A market is secured to them, and every circumstance seems inviting. While we are shivering with almost January weather, (March 20,) they have the breath of our summer, their eggs are hatching, and their foliage fine and abundant. While we, in many cases, are confined to one or two crops in a season, they can feed from April to November.

V. E.

Under the latter date, (March 11,) the writer says:

"I have some fears that our mulberry leaves will get killed, and that we shall lose our worms, for they are already hatching, and have been for several days. We are doing all we can to retard them, but shall not be able to do so much longer unless the weather changes. This is one of the most forward springs I ever saw. I have some mulberry trees in my yard which are now a fine shade. The leaves are abundant, and almost as large as my hand. The plum trees and blackberry bushes are all green, and stock is doing pretty well in the woods. These things are rather alarming, but we hope for good. I have one cocoonery 20 by 30 feet, two stories high; another 18 by 34. To these I am attaching sheds 16 feet wide. I leave the lower stories open. The only thing necessary to success, that I lack, is an ice-house for the preservation of my eggs.

"P. S.—The weather has changed for the better. It is cold enough to freeze if it were not cloudy, and our worms have ceased hatching."

From the New York Farmer and Mechanic.

SILK CULTURE—ADDITIONAL PARTICULARS.

We have more than once referred to the efforts making by Judge Ernest, of Macon, Georgia. Too much credit cannot be given this gentleman for his perseverance in this cause; and we rejoice to learn that his every effort is crowned with success. His feeding this season commenced about the middle of May. In a letter bearing date May 23d, he says:

"I have not made much silk this year: nevertheless, think I have made a favorable impression upon the minds of the people, because I have been completely successful with what silk worms I had. I have fed this year, for the first time, in an open building, and am well satisfied that silk worms do much better when fed in this way. I had no more eggs than I should have hatched and fed; but heretofore I have made too much silk—more than I could manufacture; and fearing that I should not get machinery in time, and that the same would be the case, I have chosen to feed but few, and disposed of a good many eggs; and in attempting to retard the hatching of some, I raised four or five ounces. We have made, we think, thirty pounds of silk, and have already reeled seventeen or eighteen pounds. I have heard of only one person who got eggs of me, and he has been successful, and will continue to raise cocoons if I would buy them, and that he was a man calculated to carry the thing to perfection; but, un-

fortunately, some of his domestics came across the eggs, and, thinking them of no value, threw them into the fire. He will go on next year. I also mentioned that Dr. Winn, of Monroe county, had a fine field of mulberries of twelve acres. The Doctor has been feeding silk worms for several years; and, to my great astonishment, has been unsuccessful. I was the more astonished because he had great zeal, and appeared pleased with the business. I could not account for his lack of success until last week, when I received from his brother an account of his management. He had fed all the time in a close garret. This solved the mystery at once, and I sent him word that if he would come and see me, I would instruct him to feed worms successfully, and he has promised to do so; so that I think there is little doubt but he will go into the business again; and if he does, and follows my directions, he will *certainly* succeed; and he can carry it to any extent, for he is rich, and, I understand, would delight in it. I informed you also, I think, that Major Smith had a fine field of mulberry trees, and that he has been endeavoring for several years to get some person to make silk for him; but at the time I wrote, I had been told that he had cut down his trees, and planted the field in corn. This, however, was a mistake. He had cut down his trees because they had got out of the reach of his stock, and he still wishes to get some person to attend to the business for him. The silk business will, sooner or later, be carried to a great extent in Georgia, but how long it will be before this time arrives, I cannot tell. Great numbers are already convinced that it can be made more profitable than anything we are doing, and yet few seem determined to go into it. This is strange, but it is certainly true. Ex Governor McDonald is a great friend to the silk cause. He is a great jurist, and his business and knowledge extend all over the State; and from him I expect to gain much information of the business in different sections of the State. I labor under many disadvantages, being alone. Were there others, we could have an ice-house, which a single individual can hardly afford; hence I must confine myself to a single crop. I have had eggs sent from the north, but they did not do well. If I have too many eggs, they are lost; and if too few, there is no one to supply me. With all these disadvantages, I make the business profitable. It is painful to think what great benefit might result to the country from the silk culture, and then see how little attention the subject receives. If people differed with me, I should neither wonder at them nor blame them; but they do not. Admitting the practicability and the importance of embarking in the enterprise, they leave it.

"We have, however, a few practical men among us; and during my feeding this year, I have had many visitors, and all seemed pleased with the business. One man came eighty miles, another thirty, and a third more than twenty; and they were moved by something more than mere curiosity, too.

"A poor lady in this neighborhood has made some cocoons, and, to her great astonishment and joy, I gave her \$2 50 per bushel for them; and I have already paid her \$10. She is much delighted, and says she will brag about and show her dimes to every body. The effect will be good. She could not have made half this at any thing else—and this she knows. There are many such poor families amongst us, and if they can be persuaded to go and do likewise, it will be well for both themselves and the country. I should not be surprised if there were cocoons enough raised

within reach of me next year to keep two or three reels in operation all summer, or perhaps all the year."

"A correspondent" furnishes us with another "good return." He says:

"A person purchased of me a few silk-worms' eggs, for fifty cents. They hatched July 4th, and in four weeks wound their cocoons, of a very superior quality, measuring five pecks, which weighed thirteen pounds to the bushel. He sold one bushel for $4, and used the residue for eggs, which are worth $5 or $6. He is so pleased that he intends enlarging his business—will procure more trees, and try again. He is an industrious farmer, has a family of children, and says that, for the time required, he can earn more than in any other way. His accommodations for feeding are very humble—an open shed or hovel—yet he has found success. Let others try."

A letter from Mr. John M. Sumner, of Wareheim, Pennsylvania, informs us that his success has been equal to last year, (150 bushels, we think,) and he is still feeding. Further particulars when through.

Such are a few of the favorable results which have come to our knowledge—all conducted with *reason;* and hence followed with success, as all such efforts must be.

We are informed by a note from the editor of the "Alphadelphia Tocsin," that their association will commence their arrangements next spring for making the silk business a regular and permanent pursuit, and that they have every convenience for making it extensive and profitable. We would refer similar associations to the German society, at Economy, to show to what extent it may be carried, where not less than 500 to 600 pounds of reeled silk have been produced in a single season; and this they manufacture into the finest and most beautiful fabrics—thus rendering it not merely an ornamental, but one of the most lucrative pursuits of the community.

Now that there can be no longer a doubt as to the *feasibility* and *profit* of the silk business, how long will men refuse, as many do, to embark in it, for no other reason than that it was *once* connected with speculation and humbugging?

A. C. VAN EPPS.

"STROLL AMONG THE MULBERRY TREES IN NORTHAMPTON, IN AUGUST AND SEPTEMBER, 1845."

In the midst was a spacious cocoonery, filled with an interesting family of silk-worms, of every size and age, between the egg and cocoon, taking a hasty *lunch* at the hands of the attendants, who estimated them at *one million.* Although the family was so numerous, each appeared perfectly satisfied with the fare from the larder and the field, furnished by only two attendants, to collect, prepare, and distribute the food to this numerous and interesting family: such was the order, regularity, and system adopted, that the whole process was as regular as clock work.

After passing through and inspecting the premises, a second stroll was made, in another section of the town, into an extensive *Canton mulberry* grove, which had grown the present season from three to seven feet, loaded with luxuriant foliage, sufficient for another million of worms, and was

introduced to another interesting family of *youngsters*, not of so numerous or of so large a size as some in the *millionary*, yet, as a whole, quite as interesting to behold, for they were in the last ovarious stage; and some had commenced their lunch, soon as liberated from the shell, upon the *mulberry paper* whereon they had been placed, instead of fresh foliage from the tree. It was a pleasing sight to see how readily they would pass from the common paper, on which they were hatched, to the mulberry paper. This paper had been made of mulberry foliage and bark, unbleached, for the purpose now used, and appeared to answer the purpose for which it was designed.

If this late experiment should prove successful, cocoons may be exported about the time that the New England silk convention shall hold their annual meeting, on the first day of October, 1845; but, should the weather prove adverse, a delay might extend to the time of the *national silk convention* on the 9th of October, or even later.

Another experimental crop has been in contemplation for matriculation upon the *new mode*, about the 10th or 15th of September, and, if not prostrated by General Frost making an attack upon the mulberry patch, may be expected to go up about that season of the year when Guy Fawkes laid his powder plot, on the memorable 5th of November, or some part of the month so fatal to English hypochondriacs.

I have witnessed the incipient, middle, and closing stages of feeding silkworms, and the great abundance of Canton foliage that could not or had not been used for feeding worms the present season, but which might and ought to be used for making mulberry paper, which is decidedly preferable for the steel pen, and also for the deposite of silk-worms' eggs, and for young worms when liable to premature hatching, or to obviate the destruction of foliage by frosts, in which case it is thought that the *dried leaves* might be used to finish with, being pulverized, moistened, and sprinkled with wheat or rice flour. Worms *have been* so fed with good success in the spring season. A large quantity of surplus foliage will be preserved for useful purposes, and also thousands of cuttings and eggs.

It is desirable to see the *finale* of cocoonery operations; therefore a stroll was made to an eggery—a place where silk-worms' eggs are saved for future use—and I had the pleasure of seeing a grand display of sheet after sheet, suspended and covered with silk-worms' eggs, for removal to the reception room; such were the quantities exhibited, as appeared sufficient to *wormulate* the whole of New England, and a surplus for the sunny latitudes, for which northern eggs are peculiarly adapted.

Some were deposited on large thick sheets, to absorb any possible moisture—others on very thin, pliable sheets, for mail convenience. But the most interesting sight was where the eggs had been deposited upon sheets of paper made of mulberry foliage, that, should the worms be hatched prematurely, they would have a mulberry substance to nibble upon, being prepared for that purpose.

It was interesting to witness how readily the young worms, soon as hatched upon common paper placed over the mulberry paper, would attach themselves to the latter.

The experiments now in progress may be of some benefit to new beginners, who may be supplied gratuitously with cuttings to commence operations another year, if taken away before November. A good supply will be preserved for sale.

Veritas.

For the Farmer and Mechanic.

A CHAPTER FOR SILK-GROWERS.

No business can be prosecuted with profit without a well-regulated system of operations. This is pre-eminently important in the production of *silk*—nothing can be done without it.

We have seen farmers with from one to three hundred acres of the finest land in the world, whose annual returns from the same were barely sufficient to meet the demands of the *tax gatherer*, and provide a comfortable subsistence for their families. We have seen in the same vicinity men with two-thirds less, and of precisely the same quality, not only meeting all the demands of the world upon them, and securing means for the support and education of their families, but yearly to add materially to the stock of funds accumulating for a "rainy day." Now, why this difference?

The reason is obvious: one conducts his operations with neither system nor intelligence, while the other employs both.

The same difference is observable in the culture of silk. We have been particularly convinced of this in preparing the matter for the forthcoming reports of the silk convention held at the American Institute in October last. Many cases are related where the writers had plantations varying from five to ten and twelve acres of mulberry trees, from which they had secured scarcely cocoons enough to pay for the cultivation of the soil. The failures in such cases are usually attributed to the kind of mulberry used. Others, with the same varieties and similar climate and soil, state that from one and a half to three acres they have realized from fifty to over one hundred bushels of good cocoons. These lavish their praises upon the same mulberry which the others condemned. The facts in the cases were, probably, that the trees of the former were entirely neglected, or indifferently cultivated, producing small innutritious foliage, while the latter had their trees planted on good soil, free from grass and weeds of all kinds, (which are exceedingly poisonous to the foliage of the mulberry,) and kept in a good state of cultivation during the season.

The first step towards success in the silk culture is a supply of perfect eggs; that is, eggs from healthy worms, properly taken care of at the time of laying, and secured in ice until needed for feeding. The care of the miller we shall refer to at the appropriate season. The saving of the eggs is a subject of immense importance, and has called forth various and conflicting opinions; some contending that the hatching process cannot be retarded without serious injury to if not the destruction of the worm, while others maintain that the constitution of the worm is not in the least affected by it. We concur in the latter theory, and believe it accords with the opinions commonly entertained by silk culturists of the present day.

In many instances persons have lost their eggs by placing them in an ice house; hence the lingering prejudices against this course. These failures have been owing to one of the following reasons, viz: Either they were not placed in the ice until they had passed through the incipient process of hatching, or else they were not sufficiently imbedded in the ice as wholly to exclude the warmth of the spring and summer atmosphere.

It is an easy matter, when filling your ice-cellars, to prepare a place for the box or trunk containing your eggs. A hole should be left near the middle of the cellar large enough to allow the box to sit in, and leave a space of a few inches on each side. This hole should extend down at least four feet.

Your box, having been placed in the bottom, should be covered and surrounded with straw. In taking out the eggs during the summer, it should always be done in the coolest part of the day, and the box never removed from the ice.

When the eggs are placed in the box, they should be folded up in several packages, and well surrounded with cotton batting. In this way we have kept our eggs until August, and found them perfectly dry and fine, hatching in about twelve days after their exposure. N. B—The eggs should always be placed in the cellar before the first of March. The safer and better way would be to get your ice in the latter part of January, and put your eggs in when the weather is extremely cold. On removing them for feeding, they should be gradually exposed; not permitted to receive all the whole warmth of the atmosphere before the third day.

The second thing in importance is, the mulberry plantation from which you are to collect your foliage. Many failures doubtless are to be attributed directly to the want of good, healthy foliage. The trees should be planted in rows, far enough apart to admit of easy cultivation. The ground should be kept perfectly free from all foul weeds, and as loose as possible. It should be among the last fall labor to throw up a furrow towards the roots of the trees; and in the spring return it as early as possible, that the roots may receive the benefits of the first warm rays of the sun.

Provided with eggs and foliage, we must next provide a place for feeding. The simplest protection that can be provided, to shield from sun and storms, will be found the best; and we should advise every person to adopt, without delay, the open system of feeding. A shed of the following description will answer every purpose, far better than any enclosed building that could be constructed:

For three acres of trees it will probably be found necessary to raise a tent or shed seventy-five feet in length, by twenty in width. The cheapest building of this description we have seen was made by placing in the ground three rows of posts the desired length—the outer rows eight feet above ground, the middle thirteen—and covered with common boards. The sides and ends were made of coarse muslin curtains, each about ten feet long, attached to rollers, so that the entire building could in a few minutes be exposed to as pure and free a circulation of air as in the open field. In one end of this tent should be finished off a nursery room, for hatching and bringing forward young worms, and also a bed room for the principal feeder. In this can be used Gill's ventilating cradle, or any other apparatus for feeding desired.

The nursery should be furnished with a stove for raising the temperature in damp, cold weather. Artificial heat may frequently be employed to advantage (particularly in New England) previous to the third moulting, while the worms require but little space and air.

We would here caution growers against noise. Every preparation requiring pounding or jarring should be attended to before the worms are hatched, that every thing in and around the building may be perfectly quiet throughout the whole feeding.

The feeding frames which we use, and prefer to any other fixtures we have seen, are very simple, combining all the advantages of "Gill's ventilating cradle," with none of its disadvantages, saving much time and some expense in their construction, besides being a sure defence against mice, rats, ants, and other enemies of the silk-worm. Should any of our read-

ers be disposed to adopt our plans, the following description will be sufficient:

In the first place, attach the pieces of timber designed for suspending the frames to the rafters, allowing them to come down to within two feet of the ground. These should be about seven or eight feet apart at the top, and four or five at the bottom, which will cause the frame to enlarge in nearly the same proportion with the worms, and thus prevent their becoming too much crowded. This is the chief excellence, we think, of Gill's cradle. Cross pieces should be fastened at the lower ends of the upright timbers, on which to lay boards to receive the worms from the nursery. About two inches above these boards should be placed sticks, one inch square, resting on pieces running lengthwise at the sides. These, at first, should be six inches apart, (after a few days' feeding, one-half can be drawn out;) and in feeding, the branches should be laid between them, until they are filled up to the top, when they should be laid across. After two or three days' feeding, the boards and dry branches should be removed from under the worms, and they left to feed on the branches above. If care is taken to feed no more than is needed, the brush will remain very open, allowing all the pieces of leaves and the excrements from the worms to fall directly through to the ground, from which they should be often swept out, furnishing a free circulation of air from beneath. At the sides and ends of these frames it is necessary to have something to keep the branches in order, and prevent the worms from falling off. These may be made of narrow boards or laths; between these and the brush most of the cocoons will be placed, as it secures the worms from the light, and furnishes them with places for fastening their floss, whenever they have finished eating and are ready to spin. These directions, of course, are applicable only where *branch feeding* is practised. Cocoons should not be gathered until dried; that is, in six or seven days from the time the worms begin to spin. Those designed for eggs should be selected first, taking such as have been spun by the most healthy worms. These should be closely flossed and spread out thin on the shelves in the nursery.

We now come to the destruction of the chrysales, and the curing of the cocoons, upon which the value of the silk must depend. We cannot dwell upon this point with too much care. We have received at our filature cocoons that had been almost ruined by the means used for stifling the chrysales. Our standing offer is from $2 50 to $3 50 per bushel; yet we have had cocoons sent us which would not pay the expenses of reeling and transportation. Among the means resorted to for this purpose *alcohol* is doubtless *the best*, as it not only destroys the chrysalis, but leaves the fibre of the cocoon in fine order for reeling, and is supposed by some actually to add to its original beauty. Not more than a half pint (some use only a gill, others a pint) is needed for a bushel of cocoons. They should be placed for this purpose in a tight box; first a layer of cocoons, (very thin,) then a slight sprinkling with alcohol, and so on till the box is filled, which should then be nailed up tight. After remaining in the box about twenty-four hours, they should be removed and spread out for drying, which will take several days, even in very warm weather. If the chrysales are not entirely dry, they undergo a putrefaction, which frequently injures the silk, and renders them very offensive to the reeler. Persons designing to send their cocoons to our filature are requested to adopt the above method; and as soon as dried the cocoons should be forwarded, as it is exceedingly hazardous pur-

chasing when they have been lying some months, and become very dry. Applications are now pending for several hundred bushels, and we know not what to answer. We can only say to all, as we have said to some: send your cocoons if you please; we will do the best we can by them, and pay you all we possibly can afford.

In conclusion, we would say, persevere, and success is certain. The silk cause has never been half so flourishing as at the present time. We will, as we have before said, pay all we can for your old cocoons, and warrant you a good price for your coming crops, be they large or small.

A. C. V. E.

THE SILK CAUSE IN THE OHIO VALLEY.

We believe it is not generally known to what extent the culture of silk is carried on here. It has had no "multicaulis mania" to interrupt its progress, and hence has gone steadily forward until the present time. Farmers along the Ohio have hit upon the true principle—the one by which we gain our supplies of butter, cheese, lard, &c., &c.; that is, each producing a small quantity at least. In passing through that beautiful valley during their delightful summers, it is becoming quite a common thing to see the females and the smaller members of the family gathering the foliage, and carefully bringing forward a family of silk-worms. It is found profitable, either on a small scale or an extensive scale; and we have been told that more can be made from a given quantity of land, in raising cocoons at $2 per bushel, than wheat at $1. The same is doubtless true of the entire South. If we are correctly informed, there is not less than 50,000 bushels of cocoons now annually raised in the valley of the Ohio. Should we name any course as more likely to succeed than any other, it would be that of Mr. Bliss, in his report to the Ohio legislature. He recommends every farmer to have his patch of mulberry, and every year to make it a point to raise at least ten bushels of cocoons. This will most certainly be the practice when filatures for reeling are established.

A. C. V. E.

MULBERRY TREES, SILK-WORMS, &c.

Messrs. Fleet & Starr: There are many species of the mulberry, but the Alpine is to be preferred to any other, and was very highly valued by Mr. Whitmarsh, who imported it.

The mulberry leaves are composed of five distinct or different substances—the solid or fibrous, the coloring matter, water, saccharine, and resinous substances. The fibrous, the coloring matter, and the water, excepting a very small quantity, cannot be said to be nutritive to the silk-worm. It is the saccharine matter which nourishes the insect; that enlarges and forms its animal substance, separating itself gradually from the leaf, and, attracted by the animal organization, accumulates, clears itself of all that is foreign to its own nature, and by degrees fills the two reservoirs or silk vessels which form the whole internal cavity of the silk-worm. Much depends upon the proportions which the different elements of which the leaves are composed

bear to each other. Cases may occur in which a large quantity and weight of leaves will minister very little serviceable nutriment to the silk-worm.

The Alpine mulberry, planted on high land, exposed to cold dry winds, and in light soil, produces the most healthy and nutrient leaf, and the largest quantity of strong silk of the purest and finest quality. The less nutrient substance the leaves contain, the greater quantity must the silk-worm consume to complete its development. The result is, that being obliged to perform an undue amount of labor in consuming a large bulk of innutritious foliage, the worms become fatigued, enfeebled, and certainly more liable to disease than those are which eat a smaller amount, which they would do if the leaves were more nutritious. The small silk-worm, or the eighth crop, is the best sort; this is a very superior species—it furnishes superior silk, and of a fine texture.

Cocoonery and mulberry plantation.—We have a mulberry plantation of 15 acres of trees, and a cocoonery on it, 100 feet by 25, and one plantation of 20 acres; cocoonery now in process of erection for feeding this season.

Reel, and reeling.—The greatest defect in American raw silk is, that it is badly reeled, owing to its having been done by awkward and inexperienced hands. Seeing the necessity of a public filature, to which all who grow cocoons could resort, we were induced, for the advantage of all, to establish a filatory of 8 reels, for the reeling of all cocoons which are good, and the chrysalis stifled by my method. My reel possesses many advantages over every other reel. I have made several improvements on the reel since I sold four to Mr. Van Epps. I make the reel larger for the skein to reel the silk on; have sold 12 of the reels to go to South America, and one to Canton, China. Mr. Valentine, an English silk manufacturer in this town, procured some of the silk reeled by me on this reel, (which he considered superior to any other which he has known, for evenness, color, and finish,) to send to his friends in England, as its success is improving the silk manufacture.

Northampton stands first upon the list among silk-growing and silk-manufacturing towns in America. The Northampton Association (silk factory, one hundred feet long and four stories high) promises to do much for the advancement of the silk business, as well as the prosperity of the town. They have succeeded in lustre, smoothness, and fineness of texture, not surpassed by the best Italian, as they have a French dyer. Very truly yours,

OLIVER D. PAINE.

NORTHAMPTON, *Mass.*

SILK CULTURE.

The following letter from S. A. Clemens, of North Granby, Connecticut, will be read with interest. It shows with what reception the improvements in feeding meet in our oldest establishments. This is the true plan, and must eventually be the only plan of rearing the silk-worm successfully. The old school system may and frequently does succeed, but is always attended with immense cost compared with the new, and shows that our climate is so well suited to the growth of the worm that it will grow under almost any circumstances. Mr. Clemens says:

"My grandfather planted on his farm a small orchard of the white mul-

berry, 50 or 60 years ago, from trees obtained from the minister of the parish, who raised them from seed furnished him by President Stiles, of Yale college. A few of these trees, as large as good sized apple trees, are now standing, and yield abundant foliage. Twelve or fifteen years ago my father planted an orchard of about three acres with white mulberry, in rows about one rod apart, and the trees three feet apart in the rows. The open ground between the rows having been cultivated each season, the trees have flourished vigorously, although the soil is of an indifferent quality. Silk-worms were fed from the old orchard some time previous to the last war, and the silk made into sewings, stockings, &c., in the family. During the last ten years, we have fed more or less, and always with good success in rearing the worms. We think there is no more difficulty in hatching a crop of silk worms, and carrying them through safely, if the requisite care is bestowed, than there is in raising poultry. The care chiefly necessary is, to keep the eggs in a cool dry place, secure from vermin, until they are wanted, then expose them to such heat as will bring out the *young artist;* feed him plentifully while he is disposed to eat; let him alone while he is moulting; and, above all, don't suffocate him by want of air. We have obtained the best cocoons from early feeding, and have attributed it to the foliage being fresh and better adapted to the nature of the worm than late in the season. Until the last year we had followed the old Connecticut custom of plucking the leaves from the trees for feeding, but the trees having grown so large that it was difficult to get at them for this purpose, and the tops having become so thick as to need pruning, we cut off the branches a few feet from the trunk, and stripped the foliage from them. Either of these methods, however, is unnecessarily expensive. We are now cutting out the tops of our trees, leaving the bare trunk and two or three feet of the principal branches, which are within reach from the ground, and intend, hereafter, to feed entirely from the young shoots, which will be furnished in abundance. As the shoots are taken off, others will put forth, and thus there will be a supply of fresh, tender foliage until late in the season. This seems to reform the apparent difficulty in making as good cocoons from late as from early feeding. From observations made at the cocoonery of the Northampton Association and elsewhere, we are convinced that the best mode of cultivating the mulberry is to plant them in rows about three feet and a half apart, and as thick as they can grow in the rows. The trees are kept headed down by cutting off the shoots several times in the season, as they spring from the ground. In this way the weeds are easily kept out with the cultivator; the foliage is obtained with little labor, and probably in greater quantities than if the trees were planted at greater distances, and permitted to form trunks. A neighbor of ours has cultivated the multicaulis in this way, and fed from them for several years with entire success. Instead of feeding with the shoots, however, he gathers the leaves as they put forth, and every spring cuts down the whole top to within a few inches of the ground. By spreading the litter from the hurdles upon the orchard, he has sensibly improved the condition of his soil, which was sandy and poor, and thus increased the quantity of foliage each year. The silk he produces is manufactured into sewings in his own family, and returns him at the rate of $100 per acre. Another neighbor, who cultivates the multicaulis with like success, fed from one tree one season, and found that, weight for weight, the white mulberry produced much more silk than the multicaulis. We have tried the different kinds of worms, and like the peanut best, as affording very fine,

strong silk, and perhaps equal in amount to any other variety. Some silk growers in this vicinity prefer the mammoth sulphur, as it reels more easily, and, although the silk is of a coarser quality, it answers very well for sewings. It is to be regretted that the fine lustrous silk which we can raise in this country should meet no better fate than to be made into sewing-silk, for which, abroad, only the third rate silk is used; but we are compelled to endure this until our people learn how to reel the splendid fabrics of our silk-worms in the way it deserves. The silk reel* invented by Mr. Oliver D. Payne, of Northampton, Mass., for compactness of construction, ease in joining the fibres, and the superior manner in which it leaves the skein for the hands of the manufacturers, I think superior to the Piedmontese, or any other reel I have seen, and well merits the examination of all who are interested in reeling. What I have penned [is first rate practically, and naturally worthy of imitation—V. E.] may be of less value to others than myself; but whatever may be the hesitancy now shown to engage in the silk business, I am convinced that branch feeding (in open sheds) is destined to insure its triumph; and certainly I know of no one who has had experience enough to give weight to his testimony, but will agree with me that silk culture can be made the most profitable branch of husbandry pursued in our country, cotton and sugar (of which I have had opportunity for demonstration, both at the south and West Indies) not excepted.

"Yours, very truly,

"S. A. CLEMENS."

THE SOUTH AND SOUTHWEST.

In making our proposed tour through these sections of the Union, we have concluded to begin with Mississippi, rather than at Economy, Pennsylvania. The view we shall give will be an imperfect one, and not calculated to give a full representation of what is being done here, from the fact that a great majority of those engaged in the silk culture have never reported themselves, either to the Silk Culture Convention or to private individuals. The first letter we shall present is the following, from Doctor Philips:

Log Hall, Edward's Depot, Miss.,
September 9, 1844.

Sir: Your address to "silk-growers, &c.," reached me a short time since through due course of mail. I now will endeavor to comply with your wishes.

The lady of my nearest neighbor, W. R. Gibbes, commenced last year to rear the silk-worm. Being of an experimental turn of mind, she resolved to try whether the trouble of feeding, fires, &c., &c., might not be avoidable; and, as her wont, no sooner said than done. She provided a covering to defend from rain, from birds, and to protect from the ant; this was done by the aid of an old worn out umbrella, and some netting of the kind we use

* We have this reel, with some improvements, in our filature, but have used it only a little; it contains some important principles—improvements, we think, on the old system of reeling. Our opinion in full shall be forthcoming hereafter. A. C. VAN EPPS.

for mosquito bars—coarse and torn. The worms were placed on a small multicaulis, and protected. I visited my friend several times whilst the worms were feeding, and know certainly that they were thus exposed to all weather, with no other protection, and that whilst they were there we had a very hard rain, with two exceedingly cold days for our latitude and the season—wind blowing constantly for two days, very keen, from the northwest. With all this, these worms, in a short time after the weather became pleasant, were larger than those kept in a house with a fire. This experiment of my sister-in-law proves most conclusively to my mind that worms will bear any degree of cold that we have in our climate at that season; and her spirit merits all commendation.

We feed a few worms, only to keep up *seed*, and, as usual, in an airy room, without cutting or being particular to have dry leaves—gathering with dew on them; we cleared our frames oftener than usual, using no lime, and were more successful than heretofore.

I send you specimens of our silk—not prepared with the most remote idea of sending from home, much less to *such* a spot, and to *such people.* You will make due allowance for our never having seen reeling or twisting; we have no machinery save that used on an ordinary plantation—a common *large wheel*, and a reel used for hanking thread. We use the thread we manufacture, either to make fishing-lines, or our ladies use it in their business, or to make lace for "edging" or "inserting." We find our thread far stronger, in proportion to size, than that we purchase of *foreign* make, and more even. Our machinery is too rude to offer them in competition with your northern articles, nor do I intend it; my intention being to give you something that will show the strength, and that my *adopted State* should be represented *badly* rather than not at all. The specimens sent you are—

A few cocoons of peanut variety—the first eggs presented us, as such, by Miss Emma Montgomery, of Oktibbeha county, Mississippi. These are from W. H. Benton;

A specimen of silk from those cocoons, 120 fibres to the thread, as it now is, reeled and twisted by Mrs. Wm. M. Wells and my daughter, from our cocoons;

A pair of mits—the work, from beginning to end, done by Mrs Whitford, a lady 50 years of age, and presented to Mrs. Philips. She is a very thoroughgoing lady at all improvements;

And, lastly, a fishing line made from unwrought silk, and left in the gum, thinking that the gum would keep it slightly stiff and elastic, as also less permeable to water.*

Respectfully,

M. W. PHILIPS.

James Tallmadge, Esq.

SILK BUSINESS AT THE WEST.

In the last No. we gave extracts from a communication of John W. Gill to the American Institute, in which the statement was made, that co-

*The several articles here enumerated were all received, and were admired by thousands of visitors at the last fair of the American Institute. They reflect the highest credit on the several ladies whose handiwork they are. May every success attend them.

V. E.

coons enough were made in the valley of the Ohio to keep 200 reels in constant operation during the year; from which we concluded that not less than 50,000 bushels of cocoons were annually produced. This conclusion was based on the following calculation: We suppose the reels to operate 300 days during the year, and to *turn off* 174 lbs. of silk per day, which would give 52,200 pounds per year. Allowing each pound of reeled silk to require 1½ bushel of cocoons, we have *fifty-eight thousand seven hundred and twenty five bushels of cocoons.* This calculation is a perfectly reasonable one, and will be found, by experience, to fall within the truth. We called the quantity 50,000 bushels, which we confess seems like *exaggeration*, but the source of our information is a reliable one, and the statement must be *set down* as *true*, until shown to be otherwise, for a proof of which our columns are *open.* Since the publication of the above, no little surprise has been manifested, and we have been met by numerous exclamations like the following: "Is it possible! 50,000 bushels of cocoons!!! What can possibly become of the silk? Is it exported, or are there *private* filatures and manufactories to consume this vast amount of silk?" We confess our *ignorance* of the *disposal* of the cocoons, or raw material. We have stated our authority and drawn our conclusions, and leave our readers to *investigate;* remarking that many inquiries have been forwarded to our filature from the west and southwest, asking for a market for cocoons. So far as we know, no distinct establishments have been opened there for reeling, and, judging from nearly 100 letters we have seen from silk culturists in those sections, we believe by far the largest proportion of these cocoons are worked up into sewings, &c., in the families of their producers. Owing to the imperfection of their machinery, a large proportion is worse than lost. Mr. Gill (whose factory is by far the largest at the west) says that he works up only 1,000 bushels per year. We hope shortly to be able to announce the establishment of filatures at different points along the Ohio and its main tributaries, of sufficient extent to reel every cocoon produced.

A small addition to our pecuniary facilities is only wanting to enable us to carry our plans into full and successful operation. Any gentleman disposed to aid in this way can learn particulars by calling at the American Institute and inquiring of its officers, who are acquainted with our plans, and who are quite as much interested in their success as we can be.

Among the innumerable benefits this institute is conferring upon the country should be named their exertions to advance the culture and manufacture of silk. We have been indebted to them for valuable counsels, and important facts. They have just placed at our disposal a large number of letters received at the last annual silk convention, held at the repository of the Institute in October last. These contain matter of vast importance connected with the experience of the last year, which, on many accounts, is the most important in our history connected with silk. It was the intention to have embodied these letters in a report, similar to the previous year, but this has not been done, and we shall commence next week the regular publication of them in the silk department of the "Farmer and Mechanic;" copies of which will be sent to silk-growers generally; and as this valuable journal is to be the regular depository for information on silk, and is the organ of the American Institute, containing the proceedings of the Farmers' Club, we hope every person receiving a copy of this will not only become a subscriber himself, but induce others, if possible, to do the

same. Mr. Fleet is the oldest agricultural editor in this State, and no other has such abundant facilities for the collection and diffusion of useful information. We shall next week commence a tour of examination in the Ohio valley; beginning near its rise, at the establishment of Miss Rapp, at Economy, Pennsylvania.

A. C. VAN EPPS.

SILK CONVENTION.

Reply of Dr. Daniel Stebbins, of Northampton, Massachusetts, to a circular of the American Institute, inviting his attendance at the convention of silk culturists, &c., held during the late Fair, dated Northampton, October 2d, and addressed to the secretary of the Institute. He says:

On account of the situation and public duties requiring my personal attention, it is extremely doubtful whether it will be admissible for me to accept of your kind circular invitation, and must be deprived of the pleasure of participating in the enjoyment of that interesting meeting. But I have done, and shall continue to do, all I can to advance the cause in some other way—to stimulate others to improve the opportunity. I have caused public notice of that convention to be extensively circulated in the papers, with the time and importance of the convention.

Perhaps in this way I shall have rendered as much personal service as could have been reasonably expected of a solitary individual.

I labored incessantly last winter to obtain the grant of a bounty from our legislature, to encourage the growth of silk in this Commonwealth; and through the aid of kind friends, a bounty of ten cents was obtained on cocoons for the term of three years.

I had hopes that the bounty would have excited an interest throughout the Commonwealth, to commence *anew* or *recommence* the business of growing silk. But my anticipations have been sadly disappointed. Various causes might be assigned: the previous and extensive destruction of trees, in consequence of the tree speculation, so that only a few trees escaped, and those in the hands of individuals who were not influenced by the delusive prospect of immediate wealth.

Another cause may have deterred others, who had some remaining trees on hand, the foliage of which was injured or destroyed by early spring frosts at the very time that farmers should be about their spring work, and could not wait for the reproduction of foliage; and there may have been other causes; but these alone were sufficient. Trees may be reproduced, and another spring frost may not occur next year. But we very well know that when any business has been long suspended from adverse causes, and other pursuits adopted, it is very difficult to persuade people to return to former occupations, unless by the strongest inducements of more immediate reward than can now be guarantied. As in every other great undertaking, we want the "long pull, strong pull, and pull altogether," and the same exertions in the silk culture.

The spring frosts did not materially injure the foliage of my trees, on account of the favorable location.

Although I have 10 to 12 acres of the best variety for growing silk, my

health and other business requirements prevent my personal attention to the business. The present year I leased to the Messrs. Clemens, of South Granby, Connecticut, who will attend the convention and relate their own story. There has been some silk reeled, and a large quantity of silk-worms' eggs left in my care for another year; and a plenty of good cuttings will be preserved.

Before the Messrs. Clemens closed their business, I had foliage sufficient to feed one million of worms. I have now in the care of another person 200,000 or 300,000 worms to test late feeding upon crude and frost-bitten foliage, for we have had severe frosts and sudden changes, with the mercury suddenly dropping from 60° or 70° down to 40°.

I have no confidence, however, in this *late crop*, and am confirmed in the opinion of an early crop being the most safe and sure, so as to close up the business as early as practicable in the month of July.

I am peculiarly favored with a location to keep my eggs, and have now on hand several ounces of last year's production, and there is no more appearance of hatching than at the time they were laid, more than a year since; and to test these, I have brought out 15,000 to 20,000, which hatch in 5 or 6 days, appear well, and, as the fishermen say, "*kicking*." They eat well, and I shall try the effects of unpropitious weather and crude foliage.

The crop of 200,000 or 300,000, hatched beginning of September, appear rather torpid on cold mornings, but, by the aid of moderate artificial heat the chills are removed, and they begin to eat late in the morning, and can take only three meals in the day. They have not yet had the *ague*, but I am daily expecting to find them *defunct*.

The silk statistics of Northampton, as taken this spring by a resolve of the legislature, are as follows—being furnished therewith by a person who took the list:

There are three silk manufactories, with a capital of $14,000. Ten males and forty-seven females employed.

75 to 100 lbs. of American silk, worth $500.

Over 6,000 lbs. of sewing-silk and twist manufactured, worth $41,500.

Immense quantity of silk-worm eggs raised for market by private individuals.

The weight of cocoons and quantity of reeled silk for 1845, not yet ascertained.

The New England silk convention convened the 1st instant, according to previous notice, to receive written communications, to be forwarded to New York; but none presented for that purpose. Delegates were appointed (one from each of the New England States) to attend personally, or appoint a substitute.

Since writing the above, I am notified of a public meeting, at 10 o'clock, a. m., on the 9th of October, of which I am secretary, and my services on that occasion and day cannot be dispensed with, as business of the whole county will come before the meeting. Therefore, please accept of my best wishes for success.

Very respectfully, yours,

D. STEBBINS.

Since writing the enclosed, I have received a letter from Mr. Chamberlain, of Lima, Peru, South America, who last autumn called on you for the report, not then out; he wishes to obtain one if practicable. He took out a

quantity of machinery; lost their ship, all his Canton trees, and peanut eggs; wishes me to send enough of *each* to get the variety. About this time hoped to get up his machines, and then inform me of the result of his enterprise. He had made some silk, &c., of which I think there were samples on the card I sent you last year.

His letter is dated Lima, May 24. Expects agent to come out, and can take any thing. Says there is quite an interest taken in raising silk in Lima; but most people are too timid to undertake a new business; that the climate is, above *all others*, fitted for the cultivation, and eventually will be as profitable as are her mines.

Mr. N. Storrs, a native of this place, has resided in Jamaica, with S. Whitmarsh, of Savannah, Georgia; is acquainted with the cultivation of mulberry trees; do not know that he ever fed worms in Jamaica, and south.

D. S.

We would call the attention of northern feeders particularly to the subject of winter and spring frosts, which have proved so disastrous, and blasted the prospects of so many, who, in a more propitious latitude, might have exceeded their own desires. We must take measures to secure the roots of our trees during the severity of winter, and retard our eggs beyond the season of spring frosts. The months of June, July, and August may be relied upon. A hardier variety of mulberry than the multicaulis might be adopted to advantage: say the white mulberry grafted, a nursery of which may be seen at 337 Broadway, owned and for sale by L. P. Finniels, by whom they were imported from the Cevenes mountains, in France. The statement was made several times, in the course of the Fair, that the United States produced, last year, 397,000 lbs. of silk! or about 400,000 bushels of cocoons. The *fact* must be very far from this. We very much doubt whether the aggregate would exceed, or even reach, 20,000 bushels. Where is the proof?—Editor.

SILK—LETTER FROM DR. STEBBINS.

Owing to the crowded state of our columns, we defer matter intended for the present number, and give only the substance of a communication from Dr. Stebbins, when we should have been pleased to publish it entire. His ideas on all questions relating to *silk* are practical to an uncommon degree, and we shall hope to find in him a regular and permanent contributor to this department. We know that his counsels in this cause are cheerfully given, and assure him they are highly appreciated, while we proffer to him, at all times, a space for the expression of his views. His letter, from which we now extract, may be resolved into the following brief conclusions:

1. During the ruthless destruction of mulberry trees, following in the wake of the excitement, he has been steadily cultivating them with great care and attention, presuming that they must be wanting, at no distant day, to replace those destroyed; and he has now ten or twelve acres of the best varieties of trees, with which he has been experimenting, to show up the practicability and utility of the silk culture.

2. He concludes, from his experience, that, in New England, the *one open* and *early* crop system is the most safe.

3. That the early foliage may be used for feeding, the after foliage for paper, and the inner fibrous bark from the stalks (which should be headed down annually, in order to produce large leaves) for cloth, or a quality of paper peculiarly adapted for lithographs and bank bills.

4. They suffer for want of skilful operators to carry out the plans decided to be the best.

5. He has preserved, for the present season, to accommodate new beginners, some thousands of young Cantons and Asiatic trees and cuttings, and eggs from selected cocoons. Among the older trees are seed-bearing Cantons, Asiatics, and Alpines.

6. The friends of the silk culture in Massachusetts have presented petitions to their legislature, praying for a bounty for the encouragement of the business in that State; and *he* has, with others, addressed members of the Senate and House of Representatives of the United States for the same object, but, "economy and prudence in expenditures being the order of the day," has little hope of encouragement to a branch of industry every way calculated to increase the productiveness and contribute to the independence of our country. (How much better would be the effect upon the country, and how much more it would savor of wisdom and Bible principles, to appropriate the money of the people, now employed in preparing ships of war, creating fortifications, purchasing ammunition, and "paying off" the navy, &c., for the encouragement of the production of silk.)

Dr. S. concludes by remarking that there are in the town of Northampton three silk factories, numerous plantations of mulberry trees, and the only thing needed is a supply of enterprising young men to conduct their feeding, and open establishments for the exclusive business of *reeling;* and adds, as a finale, some remarks in praise and for the encouragement of the New York Farmer and Mechanic—all of which are duly appreciated. Hope his measures for giving "a good circulation" among silk-growers, and other of our New England neighbors, may prove successful.

V. E.

SILK CONVENTION.

Mr. E. S. Bartholomew, of Portland, Chatauque county, New York, under date October 2d, in anticipation of the convention, says:

"I learn by the last No. of the Cultivator that a silk convention is to be held in connexion with the approaching anniversary of the *American Institute.* It would be highly gratifying to me to meet with you on that occasion, and participate with the friends of *home industry* in their deliberations upon this great and important national enterprise—the growth and manufacture of silk. I am a silk-grower, and it affords me great pleasure to see institutions of so high standing and character devoting a portion of their time to collect and disseminate information upon subjects of direct interest to the nation.

"I commenced the growing and manufacturing of silk in 1844. In the spring of 1843, a gentleman having a nursery of the Italian mulberry, wishing to eradicate them, gave them to me. I transplanted them—7,000

in all. In the spring of 1844, I put out an acre of multicaulis, and, on the last of May, commenced feeding. I raised 58 pounds of cocoons, which, after deducting one bushel for eggs, yielded me 6 lbs. 1 oz. of reeled silk: this I made into sewings, for which I found a ready sale.

"This season I have grown 150 lbs. 14 ounces of cocoons. First crop weighed 12 lbs. 8 ounces to the bushel; never have seen larger ones.

"Before commencing, I obtained one of the reports of the silk convention of 1843, and read carefully all the letters detailing the experience of the many who corresponded with the convention of that year. I came to the conclusion that the nearer I approached *dame nature* in the treatment of the worm, the better. Following up this conclusion, I erected me a cocoonery 20 by 24 feet, with large doors covering the entire sides, hung on hinges at their upper edge, so as to swing outwardly and form an awning. I leave these open all the time while feeding, and close only when cold and rainy; have ventilators to use at such times, and a stove to maintain a uniform temperature. I feed from seven to fourteen times per day. My rules are, the more air the better, strict cleanliness, and abundance of room. By observing these rules, do not lose 10 per cent. I now have machinery in operation for making sewings. I am satisfied that the multicaulis and early feeding will be attended with success. I am of the opinion that very many destroy most of their worms by allowing their eggs to become moist in the ice-house, or place of keeping; they should invariably be kept dry and cool. I keep mine in a tin box perforated in the top for the admission of air; this I place within a tea-chest, with the lead in, which also prevents moisture, and place them in a cavity in my cellar. If the worms could be fed all at a time, early, they would do much better, and make more silk at less expense. I use the earth for my floor, and, in case of too great heat, irrigate with water.

"The drought and intense heat of the present season have caused much disease in many parts. For several days in succession the heat continued intense, with little or no circulation of air, and the worms died by hundreds. I tried the experiment of a cold water bath, and found it to answer a good purpose. I sprinkled it on them gently with a small corn broom. I am satisfied that cold water is not detrimental, either as a bath or on foliage, if not applied too often. I shall continue to enlarge my operations and form a market for cocoons—which I shall prepare for market in raw silk. I can grow and reel ready for market at $1 56 per pound. Reeling is perfectly simple and easy, as well as all the modus operandi of the silk culture. Many in this neighborhood have entered into the business and failed. Tight feeding, and only twice a day: why not?"

REMARKS.

It is with great pleasure and satisfaction we give the results of this gentleman's *introductory movements.* He has reviewed the experience of the past, and turned it to a most profitable account. His experiment, it is true, has been on a small scale; but what he has done in this, he can proportionally equal when extended to any number of acres; and we repeat what we have often said—no branch of business can possibly be undertaken with greater certainty of success than the production of cocoons, *all things considered.* It may be introduced in Maine and Vermont, "Texas and Oregon," and almost every other section of this continent; and that, too, with profit. The difference is in favor of the warmer sections, but only in

the length of time which may be devoted to it; for silk, like wool, becomes coarser as we approach the equator, and *vice versa.* Mr. B. refers, in his letter, to the experiment of some of his neighbors and their failures, adding as the cause, "close feeding, and twice a day." "Why not?" he may well say. The *fact* that they produced a single cocoon is evidence that the silk-worm faithfully performs her task, and only needs *natural facilities* to enable her to perform it *well.* In conducting this business, we shall always observe the same difference which is observable in other pursuits. One farmer, for instance, will be highly successful in every movement upon his land; another, with precisely the same soil, naturally, and the same facilities for rendering it productive, will scarcely create a subsistence for his family. On visiting these farmers, we find the former, with his laborers, gathering *alluvials* from the *lowlands* of his farm, which he is industriously depositing over its entire surface, *while* untold quantities of the most enriching substances lie undisturbed on that of the latter; while *he* goes on from year to year adhering to the old routine of *ploughing*, sowing, and consuming. So in the culture of silk. One feeder hatches his eggs and feeds his worms through, in about the same time that would be required for the worm to pass through all his changes, in a state of nature; while another, in the same neighborhood, will pursue a course which *prolongs* the existence of the worm to twice its natural length. The result of the former treatment is a *full-sized, healthy* worm, and a *firm, heavy* cocoon. In the latter, precisely the reverse—a *small, feeble* worm, and a cocoon scarcely worth the reeling. Should we make a personal inspection of the operations of these men, we should find, in the former instance, a well cultivated orchard, a thoroughly ventilated cocoonery, and the worms supplied *regularly, both day and night*, with good nutritious foliage, and as often, at longest, as once in three hours. In the latter, we should probably find an orchard which had been a stranger to the plough or hoe, it may be for years; the cocoonery a confined "*garret* or *bed-room*," and the worms supplied with foliage poisoned by the influence of grass and weeds, at the same hours that the *feeder* takes his own food. Instances of this kind are constantly coming before us. We now recollect one directly in proof of our statements. During the present season we furnished one man with eggs, which in due time hatched and commenced feeding; we *then* supplied another individual with eggs of the same lot. The difference in hatching was about two weeks. The former of these had to bring his leaves over half a mile, and would bring at once sufficient for several feedings, and keep them wet and cool. To preserve their freshness, the latter took his leaves directly from the tree, and supplied as often as once in two or three hours. The result was, the latter completed his feeding in twenty-six days from hatching, and about as much in *advance* of the former as he had "*the start*" *of him* in the commencement. It is in consequence of these differences that we receive at our *filature* such a variety of cocoons. Two lots were brought us, not long since, produced from the same variety of worm, and fed from the same variety of mulberry; the one full-sized and perfect, yielding 20 ounces of silk per bushel, while the other required double the number to make a bushel, and gave not more than 14 ounces of silk—the fibre scarcely exceeding in strength the spider's web. The causes of the difference were precisely what we have named.

Equal variety exists in curing the cocoons and transporting them, to which we shall hereafter allude. We wish particularly to call attention

to Mr. B.'s cocoonery. The plan is a capital one. We have used canvass for the sides and ends. His arrangement we think preferable; it shields more perfectly from cold, and, as he says, forms an awning in hot weather. These things all come into account at the north: at the south they are not needed.

We shall ere long present a review of the proceedings of the National Convention of Farmers, Gardeners, and Silk Culturists, so far as they relate to silk, and exhibit the present aspect of the silk cause, as represented in that convention.

A. C. VAN EPPS.

New York Filature, 19 Stanton St.,
November 10, 1845.

LETTER FROM MR. J. W. CHAPPELL, OF LIVINGSTON COUNTY: ANOTHER YEAR OF SUCCESS.

What farmer of Livingston county can show a better return from a like number of acres?

Lima, Livingston Co., N. Y., *November* 29, 1845.

Dear Sir: Our crop of cocoons the past season amounted to about 700 pounds, produced from less than four acres of land. They were raised at three crops. The first hatched the 8th of June, and spun their cocoons the 13th of July. The second crop spun the 18th of August. The third crop did not finish spinning until the 9th of October. This last crop was the best crop of the three. A fire was kept in the cocoonery most of the time during the feeding of the last crop, keeping the temperature at about 70° Fahrenheit. Our worms are fed from five to eight times a day, being careful to feed fresh and *tender* leaves to the young worms, and *mature* leaves to those that have passed their third and fourth moulting. Our worms are cleaned every day, from the morning they hatch to the day they commence spinning.

We use the multicaulis mulberry exclusively for feeding, and consider it as hardy a tree as any variety in this country. Our plantation consists of about 200,000 of these trees, planted on high and dry land. Nothing has been done to protect them during our severe winters, and I am not aware that we have lost, during the seven years that we have had them in cultivation, a single tree.

We have reeled most of our cocoons, and have now on hand (and for sale) about 70 pounds of excellent raw silk, and have 20 or 30 pounds yet to reel.

It is expected that the bounty, which is about to expire, will be renewed at the next session of our legislature. Let the State grant a bounty for the term of ten years, to continue five years at 15 cents per pound for cocoons, and 50 cents on reeled silk, and the next five years reduced to 10 cents on cocoons and 30 cents on reeled silk, and it cannot fail to cause the permanent establishment of this business in our country. A large number of persons in this section of country are awaiting the action of the legislature upon this subject before they shall engage in the business.

Yours, &c.,
JAMES W. CHAPPELL.

A. C. Van Epps, Esq.

NEW YORK FILATURE, 19 STANTON ST.,
December 10, 1845.

DEAR SIR: Yours of the 29th ultimo came duly to hand. I learn with much gratification of your continued success in a branch of business which, I verily believe, must eventually become one of the most important in our country. Your success is the legitimate result of a steady perseverance and determination to triumph, which few have manifested. I regret that so large a proportion of those who have embarked in this enterprise have done so through merely speculative motives, with little real interest in the work, and no fixed determination to test it fairly, and prosecute it to complete success. I have, during an experience of many years as an instructor, held up to my students the *great motto*, "What man *has* done man *may do*," and so would I say as respects the production of silk in the United States.

What France, Italy, or any other country, *has* done, America *may do.* If Italy can produce silk to the value of $40,000,000 annually, it would be a libel upon American skill and ingenuity to say we cannot do the same, and as far surpass as our natural *facilities*, such as climate, soil, &c., surpass hers. This we can do; and, with enough to follow your own example, we shall do in less than a quarter of a century. You have learned through the public prints that the subject of silk has occupied the attention of the Farmers' Club of the American Institute, at its last two sessions. These meetings are to me a source of decided interest, and I doubt not their beneficial influence will be extensively felt. It is a most fortunate thing for our country that there is in this metropolis an association like this, to collect and disseminate all the important facts in relation to the agricultural and mechanical world. The subject of bounties on silk has been duly considered, and a committee appointed for the purpose reported at our last meeting the form of a memorial to the legislature, asking a continuance of our present bounty. Energetic action on the part of those interested in this business, in securing a large number of signatures, will probably secure our object. I think a petition so evidently in accordance with the public interest cannot be refused by our representatives. The subject of the mulberry was under consideration at our last meeting, as you will see by our reported proceedings. It was contended by some that a variety of the mulberry more hardy than the morus multicaulis must be adopted in our northern States. The late extensive destruction of this tree would seem to demand this. I have repeatedly recommended it, but I am not prepared to go to the expense, and exclude the multicaulis *altogether*. I should suggest the propriety of substituting for the *name* morus multicaulis that of the *Chinese mulberry*, which is its *real name*. I believe a lingering prejudice against this tree has much to do with the extensive denunciations we meet with. Your own abundant success, and that of others much farther north, prove the entire safety and practicability of using the foliage of the *Chinese mulberry* in feeding our worms.

I contend that it is perfectly safe on high and dry land, in any section of the United States; but it cannot endure one winter where the water is allowed to remain about the roots. My opinion on the subject of the mulberry has been repeatedly solicited by persons about to engage in the culture of silk; and I take this occasion to give expression to my views more fully than I did when the subject was before our club. I repeat, this is undoubtedly the Chinese mulberry; and the disciples of Confucius very

properly attribute the prosperity and solidity of an empire hitherto without parallel to the benefits derived from this tree. It was first introduced—as was the Broussa, another valuable variety of the mulberry, which ranks next to the Chinese in the quantity of foliage it produces, and which is considered much hardier, and in this respect has the advantage—through the agency of the American Institute, in 1828, about 10 years after its discovery by M. Perollet in the garden of a Chinese cultivator at the city of Manilla, capital of the Philippine islands. This distinguished botanist was sent out by the government of France on a voyage of research to the seas of Asia in the year 1818, and returned in 1821, bringing with him, besides 158 other species of living plants, what he termed the multicaulis—many stalked, or mulberry with many stems—and which he termed, by way of eminence, the Chinese mulberry. It originated in the elevated regions of China, and always prefers and flourishes most luxuriantly on similar locations. It was thence rapidly disseminated over all the plains near the seashore. From Canton, it was introduced into Manilla and all the islands of the Asiatic Archipelago, so general was the belief in its superiority over all others then employed. The reception of this tree was alike flattering. In less than two years from the introduction of the first tree into the United States, millions of money were invested in it. Silk companies were formed in almost every city and village in the land, and many of them with immense capitals. Extensive cocooneries were erected, with little or no adaptation to the end in view. Under this excitement, trees were multiplied with incredible rapidity, until the country was literally inundated. The "mulberry fever," as it was termed, saw its day, and then came on a reaction. Thousands of flourishing nurseries were torn up and burnt, and in a few months nearly all were destroyed. So great had become the prejudice against the multicaulis, that it was next to impossible to convince a man who had been "bit" that it possessed any value, or that it was fit for any thing but to be burnt. Had the trees left in the country by this excitement been carefully husbanded, we should now have been ten years farther advanced. Instead of this, we are raising but little more silk now than at the commencement of the revolutionary war.

I am of the opinion that three quarters of all the cocoons now raised are the product of the Chinese mulberry. Clark, in his work on the mulberry tree, claims for it the following advantages, as compared with the white, viz:

1st. It is full as hardy as the white.

2d. One pound of its leaves contain as much nutritive matter as a pound and a half of the white.

3d. The silk made from it is of a finer texture, and more lustrous.

4th. Its leaves are so large that a pound can be gathered at half the expense and trouble that a pound of white mulberry leaves require.

5th. It can be cultivated with infinitely greater despatch than any other kind.

I fully concur with him in the 4th and 5th, but think he may be mistaken in the other respects for which he claims superiority.

The principal advantages to which this tree is justly entitled, are, the abundance of foliage it yields the first year, and the exceeding ease and cheapness with which it may be gathered. The difference in favor of this, in my view, when compared with any other I have seen, is as five to one; besides, it is so well adapted to the system of *green feeding* now being adopted. I am told that the Broussa is as easily propagated from cuttings,

yields as abundantly and as good a leaf, and, besides, will endure our winters where the Chinese will not. If such be the case, then I think we may well give it our attention. The advocates of the Canton claim the same advantages for that. I am disposed to attribute the varied results of the experiments that have been made more to the place and manner of feeding, after all, than to the variety of the mulberry used. In no other way can I account for the *difference*, under similar circumstances. These differences must soon disappear under the modern improvements now entering into the culture of silk, and, with the same forethought as other business, meet with a like success. We must not depend upon other nations for an article so extensively used amongst us, and which we are so well calculated to create ourselves.

I know many instances where arrangements are making to enter into this business, both at the north and south, and believe we shall ere long proclaim to the world our independence of all nations, not only for the necessaries but the luxuries of life.

I am, sir, very truly yours,

A. C. VAN EPPS.

JAMES W. CHAPPELL.

CLAIRMONT MULBERRY NURSERY, &c.

FRIEND W. H. STARR: The paper thee publishes, entitled the "New York Farmer and Mechanic," which thee has been so good as to send me, has been received, and is, I think, calculated to do much good, especially in advancing two of the most important pursuits now being established in our country.

In reading the paper, I was pleased and interested by the very extensive information collected and published on the silk business; showing the immense expense incurred by the British government in bringing the same to its present very profitable standing. Their silk goods are now the admiration of the world, nothwithstanding they are unable to produce the raw material for want of a congeniality of climate.

With a little experience, the production of cocoons in our climate is as simple and easily accomplished as that of wool or flax. Filatures are indispensable, and will require time for their permanent establishment. The reeling of silk would afford pleasing employment for the females of our country.

As nurseryman, in the years 1837, '38, and 39, I raised and sold of the white mulberry trees and cuttings to the amount of $15,374. I raised, during the same time, considerable quantities of cocoons of first-rate quality, notwithstanding our inexperience. I should have continued the business but for the want of a filature where to dispose of my cocoons. Silk-reeling must be a distinct branch of the business. I understand that there are such estalishments in New England. I trust to see our stores, at no distant day, filled with fabrics of domestic make, so rich and good as to render us independent of all foreign nations, giving pleasant and profitable employment to various classes of our population.

ROBERT SINCLAIR.

CLAIRMONT NURSERY, NEAR BALTIMORE,
First month 11*th*, 1846.

REMARKS.

It is to be regretted that persons possessing the facilities and practical skill of Mr. Sinclair should, in the infancy of the enterprise, be obliged, from any cause, to vacate the field; but more especially is it to be lamented at this particular crisis, when the ranks of the silk culturists are so broken, and the cause struggling for existence.

In a previous communication, Mr. Sinclair describes his establishment and operations as follows, which we insert for the information of any who may turn their attention to this very favorable opening for prosecuting the silk culture; which advanced age disqualifies the proprietor from further attending to. We understand that Mr. S. would be glad to negotiate with some person qualified for the business, and would offer favorable terms. We extract as follows:

"I have a large stock of multicaulis and other mulberry trees, and a house, 42 by 30 feet, two stories high—both stories and garret well shelved, with a suitable cellar to preserve and cut the leaves in.

"In 1841, I had 83 bushels of cocoons raised in it—sulphur and peanut—mostly the former. In 1842, I let the house and trees to a person on shares, who made about 16 pounds of reeled silk, and upwards of 100 ounces of peanut eggs. The present season I managed it mostly myself; but, owing to many other engagements, I made only one crop, amounting to 34 bushels of peanut cocoons, which was as many as the house would hold at one time. To regulate the temperature, I have a small tight room in the cellar, with a stove in it, which enables the manager to warm the house by means of suitable conductors to convey the heated air into the different parts; but I find, in our climate, this trouble and expense may be avoided, by commencing about the first of the 6th month, after the chilly, damp weather is past. My glass windows are in one frame, and hinged so as to open or shut as the weather requires; and also Venetian shutters, so constructed that each slat, working on its own pivot, can instantly be changed from the broad side to its edge only to the light, admitting or excluding light and air, and heat—which I find very convenient. I prefer the peanut and multicaulis to feed with. I think the white Italian equally good, but the tedious gathering is a serious objection. I think it best to cut the leaves very fine until after their second moulting; then, to save time and expense, feed with branches. When ready to spin, it is best to remove them to clean shelves, and feed them plentifully with leaves. If cut, it will be better; all which will prevent their becoming *sickly*, and spinning in their own *dirt*. This is the period in which most failures occur, and may be easily prevented by a little extra attention for about a week, and the profit and success much depends upon it. At the second moulting, I have observed that only one-half or two thirds moult the first day, and the balance the next day. I find it much the best, and saves trouble afterwards, to keep these separate.

"P. S.—I found but little difficulty in raising good silk the first season, without any previous experience, and it may be raised to good profit, if manufacturers will continue to give four dollars per bushel for good cocoons; and it is well suited for families consisting of some women and children. I apprehend much wealth will ultimately come out of raising silk."

Mr. Sinclair says the business would have been continued, had there been

a market. This is but one of many instances of the abandonment of this business, when it had been most favorably introduced, on account of the same difficulty. We are happy to inform all such that there is now in operation in this city a filature for silk reeling, where cocoons are purchased at fair prices. Silk-growers would do well to avail themselves of its advantages, as their cocoons, if cured and carefully put up in barrels, may be sent a considerable distance. A large crop of last year has been forwarded from the south of Georgia. This establishment is at 19 Stanton street.

SILK IN TURKEY.

The original manufactories of silk were established before the conquest of Constantinople, at Broussa, from whence most of the raw silk is still obtained, the abundance of mulberry trees in its neighborhood being favorable to the nurture of the silk-worm. Little Broussa silk is, however, now sold in the silk bazar of Constantinople. Within the last ten or fifteen years, since the several treaties made with the Sublime Porte, the home silk trade has diminished fifty per cent. A large supply of imitation goods is received from England, France, and Italy, and the richer articles, principally manufactured at Lyons, have completely superseded those formerly received from Broussa, or manufactured at Scutari and Constantinople.—*White's Three Years in Constantinople.*

From the New York Farmer and Mechanic.

A REAL CURIOSITY—NURSERY OF MULBERRY ON BROADWAY.

This consists of five hundred grafted white mulberry trees, imported from the Severn mountains—the home of the Huguenots—in the south of France, by Mr. L. P. Finniels, of 337 Broadway. This gentleman came to the United States for the purpose of embarking permanently in the silk business, on the system of his own country. He has brought with him the best variety of trees—far superior to any heretofore introduced into this country. They are grafted about five and a half feet from the root, and shoots have grown from them from three to six feet since the last of May, and are covered with a most luxuriant foliage. He has fed a few worms, and secured a number of excellent cocoons. The multicaulis, and other varieties, frequently answer a good purpose. The silk business is a safe one with them; but a better variety, and a better cultivation of them, have much to do with the future progress and triumph of the silk business. These trees are now offered for sale, at a price little exceeding their actual cost to the importer. We advise silk-growers in attendance at the fair of the American Institute to call and examine, and bespeak for them a cordial reception, and valuable suggestions by the proprietor. Persons in the country who may wish to secure any number of these trees can have them sent safely and promptly in any direction. We shall esteem it a pleasure to aid in their distribution. Price $1 each.

From the New York Tribune.

AMERICAN SILK.

Mr. Jeffrey Hutchinson, a farmer of Long Island, well esteemed here, is now visiting our city with specimens of sewing-silk, reeled and manufactured by his daughters from cocoons produced on his farm from the morus multicaulis. We bespeak for him the favorable regard of all who consider how vastly important it is, in a national point of view, that our people should learn to grow and manufacture their own silk. It will require skill and patience to effect this, with some patriotic sympathy on the part of the wealthy and discerning; but the silk culture will ultimately be established and flourish here. Mr. Hutchinson's appears to be an excellent article, which all who want sewing-silk will do well to buy for their own sakes. He will submit it to the judgment of our principal citizens.

For the New York Farmer and Mechanic.

SILK.

Dear Sir: Although I have of late witnessed much that is interesting to me in this fertile region of country, (might be called the garden of the east,) I shall only state a few leading facts, from which you may possibly judge of what is being done along the valley of the Connecticut. Omitting, however, to say anything of the vast fields of broom corn, that make so good a return for money and labor expended, I will just remark that the silk interest, which has for so long a time received attention from some of the more enterprising and intelligent part of the community in this region, is not by any means dead—only resteth—soon to start with a double certainty of success, promising as sure a profit to the grower as anything he can raise. There are now two manufactories of sewing-silk and twist in this place, one of which I had time to visit only; and another being built, and to commence operations in the spring. Most of the silk used is imported in the raw state, as cocoons enough cannot be obtained of American growth. Sewing-silk and twist from the factory of Messrs. Holland & Conant is pronounced, by the tailors and merchants of Boston, to be equal to the best Italian, and is preferred by some, and is under contract for three years. This speaks volumes in favor of Yankee enterprise. Mr. Holland has a very simple silk reel for family use, with a traverse motion for the spooling—is easily kept in order, and costs only about five dollars. It is the best and cheapest I have seen. He also makes a silk spinner for five dollars per spindle. For family use, generally, put three spindles; it operates well and easy, and is of the same principle of those in use in his factory.

I find that orders are continually being received for mulberry seed and eggs to go south. I believe it is a well authenticated fact that eggs from the north are much the most sure in a southern climate. Mr. Whitmant, of Cuba, has his from New England, and there is likely to be a demand for them in South America. There is an abundance of trees in this section, and good opportunities for young men who would like to commence the business. Mulberry orchards to be let on shares, or sold, as will best suit.

From the New York Farmer and Mechanic.

LETTER FROM SAMUEL BARRETT, ESQ., OF FRENCH CREEK, VIRGINIA.

In detailing his experience of the last season, Mr. Barrett expresses great confidence in the silk business—considering it an enterprise of great national moment and individual advantage. He has not done much the present year; but this little has increased his confidence in, and more fully assured him of the entire practicability and ultimate success of, the whole enterprise. He has been gradually multiplying his trees for years, with a view of entering largely into the culture when they shall have arrived at maturity.

He further says: "Living at a great distance from any silk-grower, I have found it extremely difficult to obtain eggs. I have for a year or two been much retarded on this account. The past season I placed my eggs in an ice-house in March, after a considerable warm weather, and feared, in consequence, they might be injured. I exposed about half an ounce of these on the 8th of May.

"The foliage had then become quite large and abundant. On the 16th we had a severe frost, which killed all the foliage, except here and there a leaf which had been concealed by the grass. On the night of the 24th we were visited by a second frost, cutting off what had started since the 16th. Again, on the 31st, another quite as severe as either of the others. I still kept my worms alive on a few frost-bitten leaves, but they did not spin, or but few of them, although they did not appear to be diseased.

"I exposed another crop of eggs June 23d—one ounce. They hatched in 14 days. During the 1st, 2d, and 3d ages, many of them died. The remainder appeared healthy, and wound superior cocoons in 28 days. The variety the "Mirabel Inanes," I fed five times a day, and exposed them freely to fresh air. The heat was a part of the time intense. They made me 40 pounds of cocoons, weighing 250 to the pound. The mortality among my worms I attributed to a *natural imperfection* (?) of the egg, or injury sustained by placing them in ice after the hatching process had commenced. Good attention and thorough ventilation alone saved *any*. I have this season tried an experiment—the raising of the multicaulis from the buds. About the middle of May, I planted a small patch of ground with multicaulis branches, which had been buried during the winter in the open field. When I planted them some of the buds had grown an inch, so that, in handling, hundreds of them broke off. Small fibres of roots had started opposite each bud. I prepared and furrowed my ground, making the furrows two feet apart, and laying in the branches without vacancy throughout the whole length of the furrow, laying at least two branches side by side. They came up directly and grew most luxuriantly, notwithstanding it was extremely dry. The frost killed all up at the 1st of June. Wishing to ascertain how many leaves I could gather from the *patch*, I have just gathered them from one row; I found them to weigh 30 pounds, which being a fair average, the forty rows (saved from the frost) would produce 1,240 pounds of leaves. Fifty pounds are allowed to subsist 1,000 worms. According to this calculation, the forty rows would feed 25,000 worms, which should produce at least 6 pounds of reeled silk, and possibly 8 pounds. I measured the ground carefully, there being 30 square rods. At this rate I could produce from one acre 6,613 lbs. of leaves, and feed 132,000 worms; giving 33 pounds of reeled silk, worth $165, or

at $5 per pound. This is the product of one acre of multicaulis of the first year's growth from the buds. The land on which they were planted was thin, and had been but slightly manured the last year for corn.

"I once almost doubted the statement of Rev. Mr. Lane, that he had obtained 2,200 pounds of leaves from a quarter of an acre. I no longer doubt its correctness. I have in all about two acres of trees, consisting of Cantons and multicaulis. Half of them are from two to three years old. They occupy land which would produce 20 or 25 bushels of corn to the acre, and I can now gather at least 4 tons of leaves."

REMARKS.

The failure of Mr. Barrett is but *one* of many from the same cause. These disastrous *frosts* extended over the entire south. Southern silk-growers generally have depended upon a *single* crop, from the fact that they could not preserve their eggs. In Georgia, the silk-worms had just commenced feeding, when their food was totally destroyed, and many thriving plantations of trees, which afterwards yielded an abundant crop of good foliage sufficient to have made hundreds of bushels of cocoons, were entirely unemployed. Had it been known in time that the *dried foliage* of the mulberry, when moistened and sprinkled with rice flour, would answer a *good purpose*, and that eggs could safely be sent from the north during any part of the season, and were *preferable* to those saved at the south, the crops on feed at the time the frosts occurred might have been saved, and all the after-foliage turned to *silk*.

The suggestion made by Dr. Stebbins, of feeding worms from dried leaves, we deem practicable; and we advise feeders generally to preserve foliage in this way, that they may be prepared to meet emergencies which have proved so extensive and disastrous during the present year. A gentleman who has recently made a tour through Europe informed us, a few days since, that when in Switzerland he found the inhabitants prosperously engaged in feeding silk-worms from *dried foliage*, brought from mulberry-growing countries. He represented the worms as appearing finer and making superior cocoons. We should also advise persons at the south engaged in the silk business to secure their eggs during the fall and winter previous, that all their foliage may be employed. Orders for dried foliage, mulberry trees, or cuttings, and silk-worms' eggs, will be promptly attended to by the subscriber.

A. C. VAN EPPS.

From the National Intelligencer.

SILK CULTURE IN THE UNITED STATES.

Messrs. Gales & Seaton: In your European correspondent's letter of August 20, published in the Intelligencer of September 13, I find the following paragraph:

"In the Journal des Debats of the 12th instant there is a column of American statistics derived from the last report of your Commissioner of Patents. Towards the end, it is said that the culture of the mulberry and the raising of the silk-worm have utterly and ruinously failed in the United

States. 'Let France,' it is added, 'cease to fear American competition: the Union will be for her an immense market.' We may hope that the silk case is not so forlorn with you. What are the *natural* obstacles to perseverance and success?"

I assume the duty of answering the very interesting interrogatory at the close of this paragraph. There are *no natural* obstacles to *perseverance*, much less to *success*, in the silk business in the United States. The obstacles to its progress at present are purely artificial and *ephemeral.* I have had my eye upon this subject now *twenty-one* years. That I might be a disinterested witness even in the public opinion, I have kept myself clear of any pecuniary interest in the culture of silk. I have witnessed its progress, its experiments, its successes, and its failures; have scrutinized all the details of each and all; and have never yet found the slightest reason to doubt its ultimate successful establishment as one of our main staple productions.

The reason of its apparent depression at this time is to be found in the very place where it should be most rationally looked for. The late speculation in mulberry trees, called the multicaulis speculation, which I never failed to oppose, and which I never in the slightest degree advanced, caused expectations of profits from the silk business that were not only unreasonable, but wildly extravagant. The failure to realize these expectations by the many that began the culture of silk, and although a *reasonable* profit was at hand, induced its abandonment by thousands. They expected to realize a thousand dollars from an investment of capital and labor that in any other agricultural employment would have been satisfactorily compensated by fifty or a hundred. Disappointed in this extravagant expectation, they abandoned the enterprise. Another obstacle was found to its progress in the go-ahead character of our people, and their want of foresight. They raised large quantities of cocoons before there were means provided for their conversion into any useful article, and had not patience to preserve them till these means were provided. This was a great error, and placed one of the most insurmountable obstacles in the way of our progress.

Let everybody understand that the late multicaulis speculation had nothing to do with our capability to produce silk; that the true friends of the silk culture were always opposed to that speculation, and did all they could to restrain and suppress it, (the writer of this among them,) but that it had the effect of proving conclusively that the United States, from 32 to 44 degrees of north latitude, (longitude without limit,) is well adapted to the silk culture, equal in climate to China, superior to China in the enterprise, industry, and intelligence of our people, and superior to France or even Italy in every requisite for the successful culture of silk. *I* may not live to see it, but the time is not far off when even France shall be supplied with silk from this country—all Europe of course. The germ of this great interest is already firmly imbedded in our physical condition, and nothing can arrest its steady progress to an overwhelming extent. The time will come when even cotton will be second to silk on the list of our staple productions. But, before all this can happen, our people will have to learn to be satisfied with moderate but remunerative profits, and to gather these in particles so small that the common or unpractised eye would scarcely discern them. They must also learn to make up large results from small items. Did it never occur to you, Messrs. Editors, that the great difference between our

northern and southern people consists in this particular feature—they of the north are satisfied in collecting large sums from the congregation of extremely small items, almost ultimate atoms; while they of the south can never contemplate with composure anything less than a crop of a thousand bales of cotton, that is to yield them twenty to thirty thousand dollars? Even these latter, *with big eyes*, can only see a large *cotton field* of one hundred to a thousand acres; the individual plant itself is too small for their vision. They forget that it is only from the aggregation of the products of these individual plants that their hundreds of thousands of bales are made up. Now, silk is a peculiarly small article—small, I mean, in physical proportions; but there is no article so well adaped to aggregation into large masses of value.

Please say all this to your much respected correspondent in Paris. Tell him that the self-complacency of the Journal des Debats is misplaced, and bid that Journal and the people of France, and those of Italy with them, beware of "American competition" in the production of silk.

Respectfully,

GIDEON B. SMITH.

BALTIMORE, *September* 13, 1845.

From the New York Farmer and Mechanic.

DR. STEBBINS AND NORTHAMPTON.

We are pained to learn that our friend, Dr. Stebbins, has been confined to his room for more than a month past with serious indisposition. A letter from him, dated the 8th instant, states that he is so far convalescent as to resume correspondence; and, as a matter of course, his first word is about silk. We are fearful, when we consider his advance in life, and the great mental as well as physical activity which has ever characterized him, that he will fall before the great work to which he has devoted himself shall have been accomplished. But we hope that some satisfactory evidences may appear that his labors have not been in vain, and that his works will follow him. From the letter above alluded to we extract as follows:

"Some two years since, the Rev. Mr. Perkins, with bishop Mar Yohannan, from Oroomiah, Persia, visited this country; they also visited this place. I made a list of inquiries, for Mr. Perkins to answer after his return to Persia, respecting silk. I also furnished the Rev. David Stoddard, of this place, a young man of fine talents and energy, with a list of questions, to answer at his leisure. I have received from him a letter, dated Oroomiah, July 25, 1845, (of which I have written a sketch to Mr. Wakeman,) accompanied by nine samples of silk made in Persia; and when he shall visit the silk districts, or meet with gentlemen of intelligence, will give me the result. He has also sent specimens of the white and black mulberry foliage—not equal in size to our Canton, Asiatic, or Broussa, either of which sustains our winters better than the white. The Canton retains its verdure longer, and in greater perfection, than any other, and by a variety of experiments it is shown that the same quantity of foliage will make more raw silk than any other variety. This is the *genuine* tree used in China, according to the testimony of Dr. Parker and a Chinaman, when here. They examined and recognised it at once. The blossoms for seed appear before

the foliage, like the peach, and very near the ground. Only a few are seed-bearing; and should the season be favorable, I may have a good gathering. The Asiatic, like the black and white, have fruit high up on the limbs. The Canton has been found to develope its foliage earlier than any other variety. It has been found that the foliage of standard trees will become diminutive in size, when compared with those headed annually.

"Joseph Clark, of this town, (one of the pioneers, with president Stiles and Dr. Aspinwall, in the silk cause,) sowed his white mulberry trees in drills, and kept them in a bushy state, and usually cut the branches with a scythe or sickle, in all weather; and if in the middle of the day, in dry weather, usually sprinkled the foliage with water. It is well known, that by heading down mulberry trees in the spring, the quantity of foliage is greatly increased, and the quality improved."

In referring to the State bounty, Dr. S. says:

"I do not regret that the Massachusetts bounty is put at ten cents per pound on cocoons only, nor that it is only for three years. At the expiration of this time, it may be revived with more ease than if it had been fifteen or twenty cents. The legislature wish to be governed by economy, and show themselves sparing of the people's money; however, the policy is not wise.

"The European governments have expended millions to establish the culture, and are now satisfied that silk is one of the greatest sources of revenue. A *like* policy here would be productive of similar results."

The doctor then very appropriately adds:

"But what is the use of having mulberry trees of any kind, *quality*, or size, and what the advantage of legislative or individual encouragement, if nobody can be found to improve and render them productive? From present prospects, Northampton may be in a *bad fix* the coming season. The culturist at the community has left them, and another large grower, having a great offer at Boston, will leave us in the spring, and my infirm health forbids my personal attention. A fine opportunity is here presented for some person of enterprise to come forward and make his selection. If no one should appear, (a half-dozen are needed,) you need not expect much from Northampton to eke out at the next silk convention. But I am in no way disheartened, come what will; and, if my life and health are spared, shall do what I can to keep the silk ranks *full*. There is an abundance of young and old trees, cuttings, and eggs, preserved for many beginners; but it is painful to see the apathy prevailing. Many are so eager to acquire wealth, that they cannot be content with the ordinary course, but must have railroad speed. Such a spirit must not enter the cocoonery; but patience and perseverance will be crowned with success. That America will yet become a silk-growing country, is not doubted by our best men; but when? Prejudices are being left behind; and let the friends of the cause look steadily to the time when silk shall become one of our great staples, and let us keep doing; examples of perseverance may work wonders."

Nothing gives us more real pleasure than the perusal of communications of this tried and devoted advocate of the silk cause in this country. While hundreds who arose in the time of the mulberry excitement—manifesting great zeal, making great speeches and writing extraordinary things on the subject, have fallen with its fall, he has remained steadfast, and may justly be considered a "standard work"—the American *text book*—containing all

that is important and reliable on the silk question. We feel honored in being made the recipient of his favors: may they be frequent and long continued. It is, indeed, a subject of regret that Northampton, standing, as she has, prominent in the silk enterprise, should at this time be deprived of two of her most efficient men. Mr. Payne has conducted the silk department of the "Northampton Association" with great perseverance and effect; and his absence must seriously cripple their further movements, and sensibly retard their progress. Mr. P. has incurred some prejudice on account of his connexion with "a new reel," which has been considered an improvement, but which has been adopted by some to their serious injury. We have had something to do with this ourselves, but are far from attributing any blame to Mr. Payne, and believe that, under some circumstances, it may prove all he believed it to be. Instead of reeling in long skeins, as is customary, this reel runs the silk on bobbins containing about two to four ounces each. In cases where manufacturers do their own reeling, we deem it of value, and so recommended as chairman of an *examining committee* of the national silk convention held in this city in 1844. We understand that Mr. P. is now in this city, with a quantity of fine sewings of his manufacture. Where his future movements are to be, we are not informed. We direct particular attention to Dr. Stebbins's remarks in regard to the mulberry, and advise silk-growers to furnish themselves with the Canton variety as probably best adapted to our country, particularly the northern sections. It appears to be as readily propagated as the multicaulis, and as well adapted to *branch feeding*, which are the chief advantages claimed for this variety, and which have been considered so great, by some, as to entitle it to the undoubted preference. Our *review* of the silk business will be resumed. It is discontinued for the present to give place to the above, as bearing a more intimate relation to the business at the present time.

A. C. VAN EPPS.

NEW YORK FILATURE, *January* 8, 1846.

SILK.

REPORT OF HON. P. H. GREEN.

We have before referred to the following report of Col. Green, who has this year been conducting his operations in Maine with admirable success. This report was made to the New England Silk Convention, held about one year since, and has been published by this State, in connexion with the report of the National Convention of Silk Growers, held at the American Institute in October last. It is one of those careful, wisely conducted experiments, which always insure success. The opinions of the writer on artificial warmth cannot be so readily adopted. We doubt not their adaptation to the latitude of New England, but further south the open system is doubtless *the* system to insure the greatest results; and even in New England, we think midsummer feeding would prove quite as successful in open and in close buildings. We concur most fully in the great importance of governmental encouragement, in order to establish the silk business upon a firm foundation. Some general provision should be made, and every State should have its bounty, and every agricultural association its premium, for cocoons and reeled silk. We have no doubt of the ultimate success of the business *without* such aid; but should every State follow the example

of New York, Maine, and Delaware, and give fifteen cents per pound on cocoons raised in the State, the results would be astonishing; and we suggest the idea here that the friends in each State get up a memorial to their respective legislatures praying for such a provision, and for its renewal in those nearly expired, as in New York. But to the report:

The silk culture in the United States attracted my attention some two or three years ago, since which I have not been an indifferent observer of what has appeared in the public prints, and other publications relating to the subject. These, with other evidence, have convinced my mind that, at no distant period, silk will rank among the most important productions of our country. Being desirous of obtaining practical knowledge, early last spring I leased, in this town, (Northampton, Massachusetts,) about five acres of land, four of which had, five years before, been planted with from twelve to fourteen thousand Alpine, Asiatic, multicaulis, and Canton roots and cuttings. Two places were fitted up for feeding—one put under the care of a person who had fed several years, and acquired the reputation of being a good feeder. No information would be conveyed by detailing the facts attending this attempt; it is therefore only necessary to add, that it disappointed both the feeder and myself. The other was reserved for myself, and the result more than met my expectations, being wholly unacquainted with the business. A full remuneration for the labor and other outlays were not among my most sanguine thoughts—of course I am not greatly disappointed; still I may, I think, truly say, that had the other feeding succeeded as well as that under my own care, although no profit would have been realized, an encouraging return would have been made. Three ounces of eggs were hatched, and the worms carried through, feeding principally without loss, except at the time of winding, when the weather was extremely cold and unfavorable; notwithstanding, I had two hundred lbs. of good cocoons from three ounces hatched. It is deemed unnecessary to trouble the convention with detail, and I will therefore only subjoin the result of my observation and experience from this feeding, and what has been done and is now doing in other countries not so well situated probably as our own. I have therefore come to the conclusion, that with the intelligence and means practised here, silk may be made an advantageous crop even in Massachusetts. The culture of silk in France was established by the bounty of government, and is now a source of great national as well as individual wealth. Nothing is hazarded in saying, if it is established here it must be done by the united effort of government and individuals. Since the discontinuance of the bounty, thousands of mulberry trees have been dug up in this and neighboring towns; and, without prompt action on the part of the legislature, thousands now are destined to the same fate.

[The above, as will be seen, was addressed to the New England Silk Convention. The letter of this gentleman to the National Convention is of great length; and as a part of it is a recapitulation of the above, it has been omitted. A. C. V. E.]

It was my design to feed three broods of worms in succession, so as to have the last brood wind up by the middle of August. In accordance with this plan, I took three ounces of eggs from the cellar when the temperature was 54° Fahrenheit, placed them in a room where it was 60°, on the 13th of May; on the 17th removed them to a room where the temperature was

regulated by artificial heat, and ranged from 62° to 73°, until the 27th, when the hatching commenced—28th, 29th, 30th, and 31st, all hatched, or nearly so. While the temperature was at 70°, or over, the young worms were active, but became somewhat torpid when it was 64°; ranged from 65° to 70° until the 3d of June, when the whole were placed in the cocoonery. On the 4th, temperature down to 46°, worms quite torpid; supposed it all over with them; but revived on the 5th, when it was 70°, and went through perfect moulting, perfectly healthy; continued so through the 2d, 3d, and 4th; changed them after each moulting, excepting those put into the cradles, which were placed there immediately after the third moulting, and were not again changed. Some hundreds of the worms fell into the troughs of the cradles when first put into them; supposing them to be lost, no notice was taken of them till the third day, when it was deemed necessary to wash them out; accordingly, a but of water was turned into the trough at the upper end; of course the worms were carried out at the other end. This immersion, as well as fasting, had not, as was expected, deprived them of life; indeed, it had made but little change in their appearance; they were therefore all secured, by placing a sieve at the lower end of the trough, placed on dry shelves, and food given them; and, in order to ascertain whether the drenching and fasting would have any unfavorable effect, a particular place was assigned them; they went through feeding in all respects as the others, and made as good cocoons.

Judging from this and other facts that subsequently came under my observation, I feel warranted in saying, although drenching worms for a short length of time before the fourth moulting may do them no essential injury, yet nothing can be more fatal than to keep them in a wet or damp place, particularly when about forming and completing cocoons. Worms hatched May 28th and 29th were put into the cradles and on the lower shelves in the loft; the last hatched on the upper shelf, near the roof; as they approached towards maturity, it was found that all were too much crowded, and about one-third were removed to the shed. All continued healthy, and about the first of July commenced winding. On the morning of the 4th, the temperature was 50°; on the 5th, 48°; and several succeeding days about the same. This was a severe shock to the worms; indeed, it so paralyzed a portion of them (probably from 10 to 20 per cent.) that they seemed to lose the power of making cocoons, grew chubby, and died.

It was apprehended that the loft, in warm weather, would become so hot as to have an unfavorable effect on the health of the worms. But, instead of this, the least loss was on the upper shelf, where the last hatched were placed, and spun as early as the first hatched, and made quite as good cocoons. From the fact that the worms, while young, were not injured by being subjected to a temperature of 46°, and about the same, at a more advanced age, had such a paralyzing effect that a considerable portion never recovered, it is inferred that a warm temperature is more essential during the last than first age of the worms. The product of the first three ounces of eggs was two hundred pounds of good cocoons. It is deemed proper to mention that the lower story of the building is separated from the upper only by a partial floor, so as to give a free circulation of air through the whole house. The windows have sliding shutters below, and in the loft a door at each end, but no windows or other openings in the roof; also, chloride of lime was placed, in small quantities, in all parts of the building, and fine unslacked lime sifted through a bag, made of coarse cotton

cloth, on the worms, in wet, damp weather, immediately after feeding. This not only absorbed the dampness, but is believed to have contributed to their general good health.

I found, by experience, that the chrysalids could not be destroyed by the use of charcoal. A description of the plan, manner of fitting up, &c., is not thought necessary. The experiment was, however, conclusive, and it is confidently believed that whoever makes the same attempt will find that a portion of the chrysalids will not be destroyed.

A better mode of destroying them, and which proves effective, as well as every way satisfactory, is one recommended by Mr. Banne, a distinguished French chemist, which is as follows: Dispose the cocoons in a wooden box, in a stratum of six inches deep; upon each superficial square foot of these sprinkle half a pint of alcohol from a water-pot, so as to distribute the liquid equally over the cocoons; then form another stratum over these, and a further quantity of alcohol applied, and so on until the box is full; then let them be closely covered and left twenty-four hours. Instead of a box, I used a barrel that had contained alcohol, cut a space ten inches square in the head, nicely fitted a board with lists on each edge, so that when it was down all the air was excluded from the barrel. This did the thing perfectly.

With regard to the succession of crops, before mentioned, the eggs reserved for them were placed in a cellar where the temperature was 54°, and, according to the opinion of some writers on silk culture, they would not hatch without being exposed to a temperature above 60°. Contrary to expectation, as soon as the mercury went up to this point, the eggs hatched; this, too, when I was wholly unprepared for them, having neither feed, space, nor time to attend to them; of course they were lost. Not willing to relinquish my plan altogether, about two thirds of an ounce of eggs were procured, which hatched the 23d and 24th of July; these went through their first and second moulting on the sixth and twelfth days of their age, without any loss; third, nearly as well; fourth, not so successful, the weather about this time being rainy and extremely cold for the season, with constant and sudden changes, which produced torpidness of the worms, from which they never recovered; a considerable portion of them formed cocoons, but few perfected them. The first part of the season is unquestionably the best time for feeding; still it is believed, with proper attention to selecting feed, congenial temperature, say about 70° or above, (natural best; but if this cannot be had, artificial, for later crops,) may be successfully used.

Much has been said and written about open feeding; no matter how open, provided all other requisites can be had. In the humble opinion of the writer, whoever expects to produce a good crop of cocoons from worms subjected to wet or damp atmosphere for any length of time, and to a temperature below 65 degrees, will be sadly disappointed. In Lombardy, Italy, and France, the great silk-growing countries of Europe, the temperature in cocooneries is not only regulated with great exactitude, by artificial means, but the atmosphere corrected from time to time as occasion may require. In those countries the feeding season lasts but six weeks, and is as certain there as any other agricultural product.

There, the leaves from trees (not annually cut down) are used; of course, but one crop can be produced. This is no objection to a succession of crops in New England, where the trees are cut down in the spring, early shoots cut and fed to the worms, and later are constantly springing up, suitable for feeding. That the United States are at no distant period to be-

come a great silk-growing country, is more than probable; that New England will share largely in the product, is not so certain. While the foreign producers and others interested are watching with eagle eyes the progress of silk culture in this country, at all times prepared to overstock the market with raw silks, and constantly doing so for the express purpose of checking its culture here; while not one in five of our citizens who engage in it are remunerated for their labor and other outlays; while thousands of mulberry trees in this and neighboring towns have been dug up, and thousands more destined soon to share the same fate; and while the subject requires systematic investigation and revision, as well as simplification, it cannot be reasonably expected that individuals will make the necessary advance to compete successfully with such formidable obstacles.

REMARKABLE SUCCESS IN PENNSYLVANIA.

We last week referred to Mr. Summey's operations in Manheim, Pa. We have now the particulars, under date of August 21, as follows:

"We have been doing very well this summer; much better than could be expected under more favorable circumstances. Our trees were all, or nearly all, planted and re planted last spring. We have now between twelve and thirteen acres of young trees, from two to six feet high, from which we have now fed and gathered over fifty bushels of cocoons, besides those now ready to gather, spinning, and coming on; so that we have the prospect of making one hundred bushels of cocoons this season. We keep the small worms in the house; but, after the third or last moulting, remove them to the open shanties, where they require no more cleaning, but plenty of foliage, and branches or straw to spin in.

"Messrs. Carson & Rice, of Lancaster, may not reach quite one hundred bushels of cocoons; Mr. Here, between sixty and eighty; and Mr. Chrisman, from twenty to thirty bushels, which we intend reeling here."

The gentleman last named commenced last year, and made 8½ bushels. The farmers in this neighborhood are rapidly following Mr. Summey's example; and if they follow his plans fully, we predict for them like encouraging returns. We see in this one place now probably two hundred and fifty bushels of cocoons at least. We can call to mind several other places where some one farmer has thus commenced the culture of silk in this simple, natural way, and by his example induced his fellows to do the same; and this is the way new pursuits must be introduced. Let those, therefore, who are convinced that the thing *can* be done, make themselves the *first* advance, and they will not long be alone; and let all engaged in or commencing the business bear in mind that at the New York filature there is always an amount of cash in deposite for every bushel of cocoons offered; and we intend in a few days starting out on a thorough tour through the country to collect the precious materials; and hope, in anticipation of our call, that every grower will have his cocoons thoroughly cured, carefully flossed and assorted, in readiness for barreling for transportation to New York. We want 1,000 bushels, immediately.

A. C. VAN EPPS.

NEW YORK FILATURE, *August* 30, 1845.

MISSISSIPPI AGAIN.

The following statements are from Mr. W. H. Benton, of Raymond, Mississippi. It is mainly through such limited experiments that the large quantities of cocoons in our country are produced; and if we are able to supply our demand for silk by our own production, it will be by small quantities being raised by nearly all our farmers. In France, and other silk-growing countries, this is the case. There, it is quite as uncommon to see a farm without its mulberry orchard, as it is here to see one with. They raise but one crop, so that their feeding season is only of about six weeks' duration. As soon as the cocoons are cured, every bushel is carried to the *filatures* and exchanged for *cash*. In most parts of our own country, three, four, and frequently more feedings may be made in the season, with results quite as favorable as one. It will be a most happy circumstance for the United States and their population, when farmers generally make it a part of their summer's business to raise at least a small quantity of cocoons. We deem it the duty of every person, and particularly the conductors of the public press, to urge this measure upon the attention of our people. If the quantities of trees amongst us are improved to good advantage, it will take but a few years to provide a full supply. There are now many plantations unoccupied, and their owners without eggs to use their foliage; and it was with the desire of providing for the employment of these that we proposed in our last number to furnish such persons with eggs, and receive cocoons in payment at the end of the season; and we trust the proposition may be improved. Mr. Benton says: "My object in feeding worms this season was only to obtain a stock of eggs for the next, and to make such experiments as to the manner of rearing the worm as would throw light on future operations. In the limited experiment of this year, I have not been able to arrive at any satisfactory results as regards the profits of the business. It was not to be expected, nor was it a question with me. I have considered it as already settled that it is the best mode of remunerating labor *under certain circumstances;* i. e., where the laborers are unfitted for field work.

My worms consisted of three varieties—the light yellow, deep yellow, and white. Not having as yet reeled any of the cocoons, my preference for the white is merely for its beauty and size; and most of my eggs saved are of this variety. My worms were all mixed together upon the shelves, and I cannot therefore say which were the most healthy. I lost probably not more than a hundred by disease, out of about 10,000; and that loss was, I think, occasioned by the crowded state of two of the shelves. My feeding was altogether from the wild mulberry, but of various kinds. One kind I find near my house, which I think far superior to the multicaulis—the leaves are very large, very thin, tender, soft, and flexible; the young branches have a velvety appearance, which distinguishes it from any other I have seen. It however remains to be seen whether it can be easily propagated, for in this I think the grand superiority of the "morus" consists. My opinion is decidedly in favor of using cut leaves entirely, in all stages; and as I have no doubt this opinion coincides with that of the best informed, it is unnecessary to state the reasons for it."

[We saw last season at Newark, in this State, some fine experiments with cut leaves, yet could not be induced to substitute it for open branch feeding on any consideration; besides being with three quarters more cost and

labor, the chances are all in favor of the "new school" plan, because it is nature's plan, which is reason enough for its general adoption, however successful isolated cases on the other may prove.—V. E.]

"I tried various experiments with regard to *spinning*. The Greek mode is to *pile up* mulberry branches on the shelves, crossing them in all directions, and leaving the worms to spin among them, *as* they please, and *where* they please—a bad plan, for obvious reasons, to every one who has tried it. I tried two kinds of frames, made of sawed laths. By crossing the laths, boxes are formed of an inch square. Other frames were made by placing them in only one direction, thus forming grooves. This plan I find to be the best, as they are much easier made, and answer the purpose equally well.

"My expectations are fully realized. I did not expect that this year would show me what would be the profit arising from the business; but I did expect that I would show the practicability of employing time to advantage, which would otherwise have been wasted for want of ability to attend to any other employment."

[We have maintained, and do still maintain, that there is abundant unproductive labor in the United States to produce cocoons equal to our entire consumption.—V. E.]

—

SILK.—OPERATIONS AND RESULTS OF THE PRESENT SEASON.

We have been favored with a few statements from gentlemen who have been, to a greater or less extent, engaged in the rearing of the silk worm; and every item of experience corroborates most fully the opinions advanced in our last remarks in this department, viz: That to succeed, *some* degree of common sense—as *much*, certainly, as in raising a crop of corn, potatoes, or wheat—must be used; that farmers need no more expect a favorable result when their plantations are uncultivated, and hard, unnutritious food given to the worms, than to receive an abundant crop of corn, or any other grain, where the seed is sown on soil imperfectly ploughed, and afterwards left to contend with grass and weeds, until the time of harvest. We must have more consistency in this respect, before any great advance can be made. To show the importance attached to this subject by the best feeders in the world, we here give the substance of a statement made by an Italian, now a resident of this city, in relation to the course pursued by his father. He mentioned particularly one orchard of 10,000 trees. These were transplanted when about one inch in diameter, and six feet high. Preparatory to setting them out, the ground was laid out as follows: The rows were about fifteen feet apart, and the trees the same distance apart in the rows. Holes were then dug for the trees, about six feet square and two deep. The best portion of the earth thrown out was then returned to the bottom, to the depth of two or three inches, when the same depth of manure was thrown in. This is repeated; and when the hole is half full, a small conical pile of earth and manure is made in the middle, on which the tree (the roots having been carefully dressed) is placed, with a post at its side to support it. The remainder of the soil, with equal quantities of manure, is then returned. In three years these trees were nearly six inches in diameter, with large, beautiful tops; and then they commenced picking the foliage for us.

Here, the ground is prepared as for corn, and the trees laid down or set in the furrow, and generally without manuring, where they stand from year to year, in many instances, without receiving the slightest attention. The fallacy of attempting to feed silk-worms from the foliage of such trees needs no proof; and yet, from these very cases, discarding those that have proved successful, our cause has been judged and pronounced unfeasible, and the destruction of vast quantities of mulberry orchards has been the consequence.

In most cases where the trees have not been well cultivated, the hot, dry weather of this summer has rendered the leaves utterly worthless, and time and means devoted to feeding them have been worse than thrown away. An instance: A gentleman, practically acquainted with the silk business, in giving us his experience, says—

I left the city of New York about the first of May last to take charge of a plantation in Henrico county, Virginia. An extensive business had formerly been carried on here, and I proceeded with the hope of giving a new impulse to this business in Virginia, and securing an ample compensation to myself. The plantation once consisted of 30 acres, with a large cocoonery containing 14,000 feet of shelving, in which had been fed the worms from 50 ounces of eggs at a single crop. The orchard is now reduced to about 4 acres, (multicaulis,) and has not received *any cultivation* in three years. When I arrived, I found that, contrary to my expectations, I should be under the necessity of feeding such foliage as these would produce, and in an old-fashioned cocoonery, too. My first inclination was to return to the "land of the free." Having with me several ounces of eggs, however, I determined to remain and make the attempt. Another quantity of eggs soon came; but with them the commencement of an extremely dry season, which has almost literally "burnt us up," and given a September appearance even in June. I need not add that my expenses, not counting the loss of time, have exceeded several times all I shall realize from my cocoons. I concur most fully in the last article in the "silk department" of the Farmer and Mechanic, and wish it might be read and observed by every person at all concerned in the culture of silk. For the proprietor I have the highest regard, and I shall ever cherish the recollection of happy months spent in his worthy family. My confidence in the silk business remains unimpaired; and I believe that Virginia possesses all the natural facilities for becoming one of the greatest silk-growing States of this Union, and equal to any equal extent of country on the globe; but I rejoice that, like every thing else, the business must be conducted with system and consistency to insure success. Were this a plantation of my own, or should I again have charge of it, my first move would be, early in April to take up all the trees thoroughly, break up and prepare the land, increase its extent by six or eight acres, and replant the trees. In the middle I should have a place for a tent or shed, 150 or 200 feet long. With such an establishment, I am confident I should make more clear money than could by any other means be produced from any other 50 of the 500 acres of which this farm consists.

From the N. Y. Farmer.

MAINE.

The following appears in the Lincoln Telegraph, Bath, August, 7, 1845:

"SILK CULTURE.

"This product is not only attracting the attention of the legislatures of many States, but individuals, in all parts of the Union. It has been predicted by men of sound judgment and forecast that, at no distant period, silk would rank among the most important productions, and we see *no* reason to doubt the correctness of the prediction. It therefore becomes a question worthy the consideration of every agriculturist in New England, particularly in Maine. Should it be found that our soil and climate are adapted to its culture, surely an important article will be added to our products. Nothing is hazarded in saying that the mulberry tree flourishes *well* in Maine. This we know from several years' personal observation; so the foliage can be produced in any quantities; and the success we have witnessed in this town the present season leaves no doubt that a *profitable* crop can be produced. In the case alluded to, probably better cocoons, and a more healthy brood, could not be reared anywhere. Therefore, two facts seem to be established beyond a question, viz: that foliage of the best quality can be produced abundantly in Maine, and our summer is ample for the health and growth of the silk-worm.

"In Italy and France, the great silk growing countries of Europe, the crop is made in six weeks from the time of hatching the eggs. [Best feeders take their worms through in twenty-six days from hatching; in which case the feeding is kept up every two or three hours, day and night.—V. E.] It would seem, therefore, that all that is wanting in Maine is *practical knowledge*—which is not difficult to obtain—for the farmer to add a rich item to his products. The experiment we allude to, as coming under our personal notice in this town the present season, has been conducted by our fellow-citizen, Hon. P. H. Green, who deserves great credit for the deep interest he has taken in this enterprise, as well as the large amount of scientific and practical knowledge he has made himself master of, touching this whole subject. We hope Colonel Green will push his experiments another season to a still more magnificent extent. We are satisfied that no man is more peculiarly qualified as a pioneer in an undertaking which really promises so much for the future glory of the State."

The opinion of the editor of the Telegraph respecting the qualifications of Colonel Green to pursue the culture of silk can be readily endorsed by those acquainted with his views, experiments, and close observation, during his first season of feeding, and more particularly described in his able report to the New England silk convention, and the national silk convention of the American Institute, in New York, in October last. * * * He has in Northampton a quantity of superior silk-worm eggs, in fine condition for feeding. Colonel Green is a warm advocate for the application of artificial heat in cocooneries, to obviate the effects of sudden cold and chills. We are informed that last year he rented one of Dr. Stebbins's plantations, in Northampton, where he made the experiments alluded to in his report. Persons in Maine desirous of commencing the business will do well to confer with Col. G., as his close observation of the nature and wants of the silk-worm render him pre-eminently calculated to impart instruction. We

shall expect a particular account of his operations for this department soon. Success will always attend such efforts.

We have on hand further interesting matter for next week. Let all contribute their experience; for in this way alone can we fix upon the best system, and adopt it in practice.

A. C. VAN EPPS.

SILK CULTURE IN SOUTH CAROLINA.

In a letter from *Needham Davis*, of Barnwell district, South Carolina, relative to silk, he says: "The prospect of silk in this section of the country is poor indeed. The long warm spell through February and part of March brought out vegetation rapidly; the silk-worms hatched out early, and were prosperous until cold weather set in, destroying, in many places, peaches and many other fruits, and cutting down corn and much forward wheat—killing mulberry leaves. Many silk-worms were lost. I stripped bark from the mulberry tree; I took young twigs from them, and fed my worms with them. What few cocoons I have made are firm and of good quality. Few worms are diseased—not an average of five in a thousand. I shall soon state my method of rearing silk-worms. I mean to convince our citzens that they can raise silk to advantage; that the old and the young members of a family can be profitably employed at it. And hundreds will yet come into the business for their own profit, and the good of the country."

MULBERRY TREES.

We are happy to learn that the mulberry plantations of our friend Dr. Stebbins, of Northampton, are not included among those destroyed by the frosts of the last winter, as we had been informed, but are all under the superintendence of Mr. S. A. Clemens and brother, late of North Granby, Connecticut. At the west the destruction of mulberry trees has been much greater than was at first supposed. The orchard from which we did our feeding last year shows no signs of life yet, and it is feared the roots are killed. Had this been a destruction of fruit orchards instead of mulberry, the sympathy for the losers would have been very great; but as it is, few regret the loss. Said a gentleman from Moreau, a few days since, "I have lost all my trees, and it calls forth scarcely a passing remark from my neighbors. Had I lost $500 bank stock, I should have had sympathy enough. I should, however, have regretted less the loss of $3,000 bank stock than this."

The following letter is from Dr. Stebbins, under date of May 30th. The views of this gentleman are highly practical, and the country is much indebted to him for his uninterrupted devotion to the silk cause during the many difficulties which it has had to encounter, and we trust he may live to see the day of its triumph. Northern eggs are doubtless far better adapted to the south than those preserved there; and although we intend to do our principal feeding at the south, we shall feed here for eggs.

A. C. V. E.

Dr. S. says: "The season is yet rather unfavorable. We have had several frosts, which formed ice of the thickness of window glass; that of the 24th and 25th was rather severe for tender foliage. We have the ben-

efits of a bounty on cocoons to encourage the growth of silk. It was hoped this encouragement would induce many new beginners to undertake, but have not such evidence as is desirable. Another year, however, may show its fruits. When any business has been neglected or abandoned from any cause, it is often difficult to resume it courageously.

"A few out of this Commonwealth have awaked on the subject, in consequence of reading the '*Silk Question Settled.*' I have furnished to order several parcels of young seedling Canton trees and cuttings, and silk-worm eggs of the last year's crops, to individuals in the State of New York, and others more remote, and am making calculations for another year's supply, although I have not disposed of all my former stock, which can be retained until August before used.

"A gentleman from Vermont, with cocoons and reeled silk, is here, and wishes to insure a market for the new crop. I showed him your offer in the June number of the Farmer and Mechanic. He thinks the offer *too low* to send so far, and wishes for a midway market in the Connecticut valley; says there are many in Vermont who feed worms, and want a *cash* market. Cocoons have been sent here, but they do not like a barter trade.

"By accounts from various sections of country, it appears that the seasons are more irregular than in some former years, attended with sudden changes of atmosphere, and unfavorable for the silk-worm. It is a question worthy of consideration, whether we may not yet find it prudent to adopt the European practice of artificial warmth in our cocooneries, to obviate the effects of sudden changes of weather. Even the favored south may yet find a benefit of some apparatus to regulate the temperature of the cool, damp evenings, and the use of wires with reference to the effects of electricity.

"Difficulties have occurred in Jamaica, (W. I.) where the nights are comparatively cool and moist, where it may be necessary to resort to means for regulating the temperature of the evening air and moisture. A person who has fed worms in Jamaica has this day suggested to me that artificial warmth may obviate difficulties and prove highly advantageous, and also using silk-worm eggs from America, especially those raised in New England, in preference to any which have been propagated in the island. The creolizing system has not answered the expectation. Such was the result of experiment in the Sandwich islands, where the experiment was made of crossing the American with the native or China eggs. In our own country, would the northern eggs be better adapted to the south than eggs raised south? I have had silk-worm eggs from the south; and especially some sent me by the unfortunate Dr. Perrine, from Indian Key, Florida, proved a failure, from whom also I had a great variety of seeds which had not been sufficiently acclimated according to his most sanguine expectations; but all the seeds, plants, cuttings, and eggs, sent from here to him, fully answered the expectations.

"It is well known that Mr. Whitmarsh introduced a species of mulberry seed from Italy, gathered near the Alps, and here called Alpine mulberry. From this seed he raised large quantities of seedling plants, and transferred them to Jamaica for feeding worms upon its foliage, and, after a few years' use, found the leaf too hard and crude for the worm; and it is now understood that he has rejected them entirely, and has substituted the multicaulis and Canton as more congenial to the silk-worm.

"A person who took with him Canton seedlings from this town to Jamaica informed me that they flourished astonishingly, and grew in one season to

such a height as required heading down every three months. Such was the case in the Sandwich islands.

"As with fruits, so with the feed for silk-worms; there may be different degrees of goodness in the foliage, as the *good*, *better*, and the *best*. I have tried almost every variety, and have the vanity to believe that by actual experiment I have discovered the most profitable varieties for feeding worms adapted to this or any other climate.

"If our farmers should adopt the sentiments of Gen. Tallmadge, as expressed before the Farmers' Club, 'that silk is the most interesting subject that could be brought under the consideration of this nation—that no country on the globe, except China, can compete with the United States,' who could decline a trial of its merits, not only to insure personal prosperity and wealth, but to open an immense source for national revenue? The above sentiment is worthy of him who uttered it, and of every patriot in America, and should be promulgated throughout the whole length and breadth of the land."

From the Maine Farmer.

SILK CULTURE.

Our operations thus far have been on a small scale, but we believe that, under judicious management, the rearing of silk-worms may be extensively pursued, even in this cold region of frost and snow, with as good a chance of success as in the culture of corn, wheat, or any other product of the farm.

We have five hundred white mulberry trees of eight years' growth, which occupy one-fourth of an acre of warm, sandy soil, that was cultivated, while the trees were small, in potatoes, beans, &c.; only ten common cart-loads of stable manure having been applied since the trees were put out. Have a few hundred of the multicaulis mulberry also, but have used none of the foliage for feeding worms. Think they will not flourish well here.

In 1843 we fed 12,000 worms, which spun good cocoons, but accidentally lost 5,000 of them by fire. From the remaining 7,000, which weighed 28 lbs., we manufactured 1,000 skeins of sewing-silk. In 1844 we fed 20,000, but, from a want of experience in preserving eggs, the worms were unhealthy, and made poor cocoons: manufactured 500 skeins of sewing-silk, and seven handkerchiefs, worth $1 25 each. The past season we fed 22,000, which did well: made 2,500 skeins of sewing silk, 12 handkerchiefs, that were pronounced "good," and sold very readily at $1 25 each, and a mantle of superior texture, worth five or six dollars:

2,500 skeins of sewing-silk, at $3 per hundred - -	$75 00
12 handkerchiefs - - - - - -	15 00
A mantle - - - - - - -	5 00
State bounty - - - - - - -	9 00
	104 00
The expense of attending the worms, spinning, weaving, &c., at $1 per day, amounts to - - - - -	60 00
Profit - - - - - -	44 00

As to the profit of the silk culture, we are not prepared to speak with assurance, but would remark, that while the foreign article is by the community preferred to the domestic, the manufacture of sewing-silk cannot be profitable.

We would advise those engaging in the business to establish fixtures for reeling, and acquaint themselves with the process, as the "raw silk," well reeled, will always sell readily at a fair price.

Enclosed, for your inspection, is a fair specimen of the sewing-silk manufactured the past season as above.

J. S. LONGLEY.

NORRIDGEWOCK, *January*, 1846.

NOTE.—We were much pleased, on receiving the above communication and the specimen of silk enclosed. The specimen is well manufactured, is even in twist, and has a good lustre. We hope to hear from others who are engaged in this business. Let us know what progress you make. We suspect that Mr. Longley is situate farther north than any other silk-grower in the Union.

Total -	762	408	354	191,324	204,913

Note.—It is to be remarked that the cistern bottoms resulting from this crop have not been re-boiled by the planters as heretofore has been the case; they have been bought up by the refiners at higher rates than the planters could realize by working them over. This item is estimated to be equivalent to 5 per cent. addition to the number of hogsheads of sugar, and would swell the crop to full 200,000 hogsheads.

A large quantity of cane has been sold in the field to make plant for new plantations; a considerable quantity was lost by overflow in the summer, and some for want of fuel to work it.

There has not been the usual quantity of molasses made in proportion to that of sugar, owing probably to the cane having acquired a higher degree of maturity; and it is supposed the average yield has not exceeded 45 gallons per 1,000 lbs. of sugar, or, in round numbers, about 9,000,000 gallons.

It will be observed, from the foregoing statement, that there are in operation in this State 762 sugar mills, of which 408 are worked by steam

engines, and 354 by horse power; the number of planters about 900; some of the smaller estates joining their neighbors in one sugar-house.

There will be a large increase of sugar plantations in this State within the next two years. Preparations are making for full 60 or 70, the low prices of cotton having induced many growers of this staple in the parishes of Pointe Coupee, West Baton Rouge, Iberville, St. Landry, Opelousas, &c., to turn their attention to sugar.

P. A. CHAMPOMIER.

New Orleans, *April* 21, 1845.

When I published the preceding statement of the crop of sugar in Louisiana for the year 1844–'45, I had only in view the one object of obtaining the correct details of the crop, in which I succeeded to my entire satisfaction; but I gave little or no attention to other points connected with the actual condition and future prospects of the culture of cane. It was not until I was making up for publication the details I had connected as to the crop, that it occurred to me to make any remarks on the two points of the number of proprietors of the existing plantations, and the probable number of new ones then just opened, or opening; both of which I was, under the circumstances of the case, compelled to do by a rough and vague estimate, principally founded on information received from others.

Since then, however, I have devoted much time and attention to both these points; and having found by my particular investigation that my previous estimates were very erroneous, I deem it a duty to correct the errors, particularly as my publication has been extensively referred to and quoted as authority through the Union. For the then existing 762 plantations, I estimated there were 900 proprietors: instead of 900, however, I find there were 1,200 on the old plantations, being distinct families, or heads of families, who are the owners of these estates, and principally depending on them—this entirely exclusive of overseers, sugar-makers, engineers, carpenters, coopers, blacksmiths, &c., as well as all other families who are connected with the culture of cane in this State.

My error was still greater in my estimate as to the new plantations. I have as yet completed this investigation only for the following seventeen parishes, for which I give the details, viz:

	Old mills.	New mills.	Total mills.	No. planters.
Pointe Coupée - -	5	32	37	41
West Baton Rouge - -	19	31	50	69
East Baton Rouge - -	18	17	35	52
Iberville - - -	69	41	110	169
Ascension - - -	48	15	63	98
St. James - - -	67	9	76	185
St. John the Baptist - -	55	6	61	143
St. Charles - - -	37	4	41	88
Jefferson - - -	24	4	28	48
Orleans and St. Bernard -	23	2	25	42
Plaquemines - - -	36	7	43	70
Bayou Lafourche—Assumption	62	72	134	206
Lafourche Interior - -	49	39	88	159

Terrebonne - -	- 42	26	68	87
Attakapas, St. Mary -	- 147	31	178	287
St. Martin - -	- 36	31	67	106
	737	367	1104	1850

The statement may be relied on as correct, for not only has it been made out with care and punctual personal investigation, but I have also recorded, and in my possession, the name of every proprietor of each of the above 1,104 old and new sugar plantations in each of the above parishes respectively.

It thus appears that in these 17 parishes there are 367 cotton plantations which have been changed into sugar estates. But even this does not show the full number, as many other small cotton-growers have also abandoned that culture for sugar; but not having the means to erect sugar works themselves, all grind their cane at the mills of their immediate neighbors, and these small estates are not reckoned among the 367 new plantations.

In the three other parishes, Vermillion, Lafayette, and St. Landry, where there were 25 old plantations, I have not investigated the number of new ones, but, from the information I have obtained, there must be 25 to 30, or even more.

In the parishes of Rapides, Avoyelles, Calcassieu, Catahoula, and Concordia, arrangements were being made for more than 200 new sugar plantations, but the most part of them have been suspended, and cotton will be mostly cultivated on them for another season, until the action of Congress respecting the tariff is ascertained. Still there are, however, 70 to 80 that are actually opened and going into operation in those five parishes, and all those who suspended the change of their culture are fully provided already, even at great cost, with seed cane for planting.

Of the above-named new plantations, but a certain number will produce more cane than they will respectively require for replanting this season, and add but a little to the present crop. But a very large number will be in full operation for the next crop of 1846–'47, and all of them for the crop of 1847–'48.

Seventy-two engines for sugar mills have been introduced in the State this year, coming from the manufactories of Pittsburg, Cincinnati, Louisville, New York, Philadelphia, and Richmond: some very costly ones from New York and Philadelphia.

There will not be less than 130 put up this next season—by Pittsburg, 35; Cincinnati, 72; Louisville, 10; New York, 10; Richmond, I know of none; New Orleans, 15.

P. A. CHAMPOMIER.

New Orleans, *November* 24, 1845.

From the Planters' Banner.

THE SUGAR MARKET.

The 1st of September being the commencement of a new commercial year, the New Orleans Price Current, in accordance with custom, takes a

retrospect of the most important business operations of the New Orleans market during the season which has just terminated, and offers some remarks upon the prospects of the opening year. We give the remarks on the sugar market, which must prove highly interesting to our planters:

"In our annual report of first September last we stated, in reference to the then growing crop, that up to that period the prospect was of the most flattering character for its early maturity and unusual abundance, and we have now to remark that the result has well maintained our expectations, as a continuance of highly favorable weather throughout the season enabled our planters to make the largest and best crop ever produced in Louisiana. In regard to the amount of production, we have already given it in a former number, and again avail ourselves of the published statement of Mr. P. A. Champomier, who gives the product of each plantation visited, and the result is 191,324 hogsheads, which Mr. C. estimates to be equal to 204,913,000 pounds. Besides this, Mr. C. states in a note that 'the cistern bottoms resulting from this crop have not been generally re-boiled by the planters, as heretofore has been the case. They have been bought up by the refiners at higher rates than the planters could realize by working them over. This item is estimated to be equivalent to 5 per cent. addition to the number of hogsheads of sugar, and would swell the crop to full 200,000 hogsheads;' so, according to this best available authority, we place the crop of 1844 at 200,000 hogsheads—equal, in round numbers, to about 215,000,000 pounds, and exceeding the crop of 1842 (previously the largest) by 60,000 hogsheads. The first arrival of the new crop was on the 3d October, establishing the early maturity of the cane, the first receipts of the previous year having been on the 22d October. Some few small sales of the earliest arrivals were made at 6 and 6½ cents, but prices soon gave way as the receipts increased, and by the latter part of October the extreme rates were 4½ and 5½ cents. The market continued generally dull, with increasing stocks and declining prices, until the early part of November, when the demand opened with some activity, both for the north and west, at an extreme range of 3½ and 5¾ cents. For more than a month subsequent to this period the market continued irregular, though generally much depressed under a large accumulation of stock, when about the middle of December an active demand again sprung up, principally for shipment to the north, at 3 and 5½ cents. A period of dullness again ensued, and by the 1st January prices were down to 2½ and 5¼ cents extremes on the levee, the market continuing extremely heavy until late in the month, when some speculative movements at the north, based mainly upon the very large deficiency in the crop of Cuba, (said to be about 600,000 boxes, or considerably more than the whole crop of Louisiana,) gave a renewed and more active impulse to the demand, and extensive purchases were made, principally on speculation and for shipment to the north, at 2¾ and 5¼ cents on the levee. At this point, also, large operations were entered into on plantation, and a number of crops were disposed of at prices ranging from 2¾ and 4 cents, the prevailing rate being 3½ cents for fair crops. At the commencement of this demand the market, as regards prices, had reached about the lowest point of the season, and here began the upward impulse, which, with a generally good demand, gradually carried prices up to 5½ and 7 cents on the levee, and 5¾ and 6¼ on plantation, a point which they reached about the middle of April, the great bulk of the crop having passed into second hands some time previous. Here, in consequence of unfavorable advices from the north,

a reaction took place, and the market remained in a very dull state, with gradually declining prices, until the latter part of May, when they had again fallen to $4\frac{1}{2}$ and $6\frac{1}{4}$ cents on the levee, and $5\frac{1}{4}$ and 6 on plantation. From this period excessive dullness prevailed up to the latter part of July, when improved rates at the north directed orders to this market, particularly for the ordinary to fair qualities; and these, acting upon a reduced stock, again produced a reaction in prices, which have since materially advanced, the closing rates being 6 and $7\frac{1}{4}$ cents for fair to strictly prime, the common qualities being all disposed of; and the whole quantity in the State is now estimated not to exceed 2,500 hhds.

"The crop, as above stated, with a stock on hand 1st September last estimated at 2,000 hogsheads, makes a supply of 202,000 hogsheads, the distribution of which may be stated as follows: Exports, including those from Attakapas, equal to 107,000 hogsheads, western States 70,000, domestic consumption of the city and of places in this and neighboring States, furnished in small parcels, of which there is no record, 12,500; taken for refining in the city and State, 10,000; stock now on hand in the State 2,500; total, 202,000 hogsheads. This statement we are persuaded approximates to correctness, though as regards all the items except the first we are left entirely to conjectural estimates, as there are not, nor in the nature of the trade can there be, any positive data for the quantity taken by the west and south. It will be seen that of the amount exported, the Atlantic ports have taken 101,000 hogsheads against 30,000 hogsheads last season.

"In regard to the growing crop, we understand that it is not generally considered as far forward in its progress by some two weeks as it was last year at the same period, a circumstance which may prove of serious detriment, though we are happy to have it in our power to state that from present appearances the promise is flattering for an abundant yield; and should the weather continue of as favorable a character as it was last season, there seems a strong probability that, what with the extension of cultivation and the improved modes of culture and manufacture, the coming crop will be the largest in quantity and best in quality of any yet produced in Louisiana. With all this flattering promise, however, it should be held in remembrance that the cane culture in these latitudes is very precarious, and an early frost or a severe hurricane might blight the present encouraging prospects of the planter to a serious extent. As an evidence of the remarkably fluctuating character of the production, we annex a statement of the crops for a series of years, by which it will be seen that while the crop of 1834 was 100,000 hogsheads, the succeeding one, that of 1835, fell to 30,000; and further, that the last crop exceeds the one immediately preceding it by 100,000 hogsheads:

Crop of 1844	200,000 hogsheads.
1843	100,000
1842	140,000
1841	90,000
1840	87,000
1839	115,000
1838	70,000
1837	65,000
1836	70,000
1835	30,000

Crop of 1834	- - - -	100,000 hogsheads.
1833	- - - -	75,000
1832	- - - -	70,000
1829	- - - -	48,000
1828	- - - -	88,000

"As regards the prospect of prices, it will be borne in mind that the ascertained deficiency in the crop of Cuba was the main cause of the recovery of the market from great depression during the past season; and as the accounts from that island state the growing crop to promise the usual average production, a similar favorable influence from that quarter cannot be expected to operate upon the coming crop of Louisiana. Nevertheless, the extension of consumption in our own country, and the opening of the English markets at a reduced duty, will be likely to protect this important staple from so great a depression as would otherwise be consequent upon a large production."

New Orleans, *March* 1, 1845.

Dear Sir: I do hereby certify that the annexed statement of my last crop made on Myrtle Grove plantation, and which it is your intention to have printed in the report of the Patent Office, is true and correct; and I do further say that your apparatus has exceeded, in all respects, my expectations. I have, in consequence, contracted for another apparatus for another plantation of mine, and with which I intend to make my next crop into loaf sugar.

Very respectfully, yours,

T. J. PACKWOOD.

Mr. N. Rillieux.

N. RILLIEUX'S PATENTED APPARATUS AND PROCESS.

Myrtle Grove estate—Statement of the sugar crop, 1844–'45.

The total crop amounts to 829 hogsheads, to wit: 128 hogsheads obtained by the old set of kettles, and 701 hogsheads by the new apparatus.

The 128 first hogsheads have been sold here, in November and December, 1844, at the average price quoted for fair sugar during the same period in the New Orleans price current. The same average price ought to be taken, in consequence, for the following months, as a correct expression of the prices which the owner of the plantation should have obtained for his sugar. Would he have made his entire crop by the set of kettles, and without using the new apparatus? Such are the prices adopted in the following statements, to establish a fair comparison between the proceeds of the two processes.

The 701 hogsheads by the apparatus are represented by—

177 hogsheads sold at New Orleans in November and December, 1844, and January and February, 1845.

202 shipped for different places, viz:

New York, 10 hogsheads, sold at $6\frac{7}{8}$ cents.

Boston, 10 hogsheads, sold at $6\frac{3}{8}$ cents.
Charleston, 50 hogsheads, sold at $7\frac{3}{4}$ and 8 cents.
Philadelphia, 117 hogsheads—no report.
Liverpool, 15 hogsheads, do.
322 hogsheads yet unsold.

Two per cent. has been reported as the loss in the weight for the above shipments.

The monthly sales made in New Orleans of 128 hogsheads from the set of kettles, and of 177 hogsheads from the apparatus, are as follows:

Sales of sugars.

Time of the sales.	Set of kettles.—(*a*)	Apparatus.—(*b*)	(*a*) Average prices of sales of sugar.*	(*b*) Average prices of sales of sugar.†	Average prices of sugar, *fair*, as per price current.‡
1844 and 1845.			*Cents.*	*Cents.*	*Cents.*
November -	70 hogsheads, = 77,937 lbs., sold for $3,333 28	10 hogsheads, = 12,130 lbs., sold for $782 67	4.28	6.45	4.25
December -	58 " = 64,139 " 2,630 76	60 " = 70,793 " 4,486 73	4.11	6.33	4.13
January -	- - - - -	56 " = 63,629 " 3,720 72	-	5.84	3.68
February -	- - - - -	51 " = 58,543 " 3,566 00	-	6.09	4.00
	128 " = 142,076 " 5,964 04	177 " = 205,095 " 12,556 12			

* General average of the prices of sales of sugar, 4.19 cents.
† General average of the prices of sales of sugar, 6.12 cents.
‡ General average of the sugar, fair, by price current, 4.01 cents.

The proceeds of the crop from 370 acres of cane, to wit, 829 hogsheads of sugar and 361 barrels of molasses, as follows:

	Hogsheads and barrels.	Pounds.	Gallons.	Price.	Total.	
Set of kettles.				Cents.		
87 acres { Sugar - - -	128	142, 130	-	4.19	$5, 964 04	
87 acres { Molasses - - -	221	-	8, 832	18	1, 589 76	
						$7, 553 80
Apparatus.						
283 acres { Sugar, 1st quality -	561	645, 150	-	6	38, 709 00	
283 acres { Sugar, 2d quality -	140	154, 000	-	5	7, 700 00	
283 acres { Molasses - -	262	-	10, 500	18	1, 890 00	
						48, 299 00
						55, 852 80

NOTE.—The molasses obtained by the set of kettles is in the proportion of 69 gallons per hogshead of sugar. By the apparatus this proportion is reduced to 15 gallons. The price quoted at 6 cents for 1st quality (apparatus) sugar, is below the general average of the prices of sales of sugar, (6.12 cents.)

The following averages have been obtained, during the time of the crop, from the same quantity of cane juice:

By the set of kettles—sugar, 1,000 pounds; cistern bottoms, 80 pounds; molasses, 776 pounds.

By the apparatus—sugar, 1st quality, 1,000 pounds; sugar, 2d quality, 280 pounds; molasses, 190 pounds.

From examination of the above average productions and average prices, it must be answered that the proceeds of the whole crop of 1844,–'45, taken off in the two ways, should have been as follows:

By the set of kettles.

	Hogsheads and barrels.	Pounds.	Gallons.	Price.	Total.
				Cents.	
Sugar - - - -	649	721, 130	-	4	$28, 845 00
Cistern bottoms - - -	50	57, 680	-	$2\frac{1}{2}$	1, 442 00
Molasses - - - -	1, 120	-	44, 781	18	8, 060 00
Crop—total amount - - - - - -					38, 347 00
Balance - - - - - -					21, 794 00
					60, 141 00

By the apparatus.

	Hogsheads and barrels.	Pounds.	Gallons.	Price.	Total.
				Cents.	
Sugar, 1st quality - -	697	802,061	-	6	$48,123 00
Sugar, 2d quality - -	176	193,228	-	5	9,661 00
Molasses - - -	328	-	13,095	18	2,357 00
Crop—total amount - - - - -					60,141 00

In the above account the economy of the fuel is not mentioned, though it is an important item; for, by the new process, there is a saving of two-thirds. The apparatus requires, with the feeding of the steam-engine, one cord of wood per hogshead, and the refuse cane is more than sufficient.

The next crop at Myrtle Grove shall be taken off in white sugar in hogsheads, and another apparatus shall work also, but to take off the crop in white loaf sugar at Bellachasse, another plantation, of which T. J. Packwood, esq., is joint owner with T. P. Benjamin, esq.

New Orleans, *March* 1, 1845.

SUGAR CANE--ITS CULTURE IN LOUISIANA.

Mr. L. Tucker: The plants we cut and matlay in beds during the autumn, usually in October, previous to the sugar-making season, and before the canes are injured by frosts. Often the unripe tops, which would otherwise be thrown away, are winrowed for plants. The best plant cane we usually save for plants, because they are the easiest put up and the quickest planted; for time and saving of labor are money. Besides, by plantnig the whole stalk, it grows more vigorously than the tops, especially in a dry season.

After the sugar-making season is over, which usually is about the first of January, we prepare our land designed for cane, by ploughing and harrowing, breaking it from four to eight inches deep; the stiffer the land the deeper the ploughing is necessary to protect it from drought. Thus prepared, the ground is laid off in rows, with a two-horse plough, about six feet apart, (some plant as close as four feet.) In these furrows a double mould-board plough, with one horse, is run, in order to clear the furrows of lumps and sods, and also to deepen and widen the furrows; as it is necessary to put the plants several inches below the surface, otherwise the cane would require too much hilling, especially the second and third years.

The plants are now taken from these mats, and the leaves stripped off, placed in carts, carried and tipped out on the prepared land, and laid lengthwise in the furrows. We plant three canes side-by-side, or triple; some say one and a half is sufficient. The closer the rows, the less each would require. We now pass along with a cane knife, and cut the cane in pieces, say from two to three feet in length, in order that the canes may lie more level, and because more eyes will vegetate. Being thus placed,

they are covered with a plough to the depth required, from one to three inches, over which a light harrow may be passed. Many prefer to cover with the hoe. Soon as the freezes are over in February, the cane is ploughed, running the bar each side the cane, and throwing the furrows from it; the cane, beginning to come up, is scraped, (so called;) if covered too deep, the earth is taken off, usually with a hoe, sometimes with a harrow or other machine, and cleaned from grass and weeds. In a few weeks it is again ploughed and hoed, and again, when necessary, a little earth put to it when required.

The cane by April or May has come up thick in the rows, but usually not so thick but that the stalks, when about a foot and a half or two feet high, send out many new stools or shoots from the bottom of the stalk, and, if they come out early, grow and mature equal to the main stalk. It is usual to give it three or four workings, and in the last to hill the cane three or four inches, and sufficiently high to protect the lower eyes on the stalks from freezing in the winter. Those eyes vegetate next season, and produce nearly equal to the first season on fresh land, and so again the third year, and often longer. Cane is injured by hilling before the stools are sufficiently high, and should receive the last working soon after it is about three feet high, in order to afford more time for ripening. After this period, say in June, it grows very rapidly; the joints begin to appear, and the lower joints begin to ripen—to sweeten; and by the middle of October usually ripen from two to four feet from the bottom, and continue to ripen about a joint (or six inches) a week, till they are cut for the mill, or till the freeze comes; or till they are cut to winrow, in order to secure them from an anticipated freeze. About the middle of October we commence making sugar. Each hand takes a row; first cuts the tops of the stalks off just below the green leaves, and drops them on the ground or lays them in winrow, if designed for plants; then, with the knife, (the blade of which is about 18 inches in length and two inches in breadth,) the dry leaves are stripped from the stalks, and the cane is cut close to the ground; the left hand at the same time has hold of the canes thus cut, and places them in small heaps, convenient for loading into carts, drawn by horses, mules, or oxen. Other hands load the cane, and it is hauled to the mill.

The cane fields are all ditched, usually every acre in width, with cross ditches about every five acres. No water is allowed to remain on the surface. The cultivation is as simple as that of broom corn, and the young shoot far more vigorous.

Cane stalks usually grow from 6 to 9 feet high. The leaves shoot up two or three feet higher. Cane ripens in favorable seasons within 12 or 18 inches of the top. You will perceive we plant one-third of our cane land or crop yearly, two-thirds coming from the ratoons.

S. TILLOTSON.

New River, La., *August*, 1844.

From the Floridian.

FLORIDA SUGAR—LETTER FROM F. P. MILLER.

We have been shown a specimen of sugar manufactured by F. P. Miller, esq., of Jefferson county, (referred to in the letter below,) which is by

far the finest sample of Florida sugar we have ever seen. It is nearly equal in whiteness to the Havana box, and is superior to the sugar brought here from New Orleans. Had we the capital to erect proper works, sugar would soon become no small item in our exports. As it is, however, our planters will soon be able to manufacture not only sufficient for their own use, but to supply the demand of our home markets. The annexed letter from Mr. Miller, which has been kindly furnished us by Gov. Moseley for publication, contains some hints which may be useful to those engaged in the cultivation of the cane. We would respectfully suggest to those of our planters who have had experience in the manufacture of sugar, to communicate the result of their observations to the public. We should be happy to extend the use of our columns to any one who would favor us with articles upon sugar, as well as upon the culture of tobacco, &c.

Jefferson County, *September* 1, 1845.

Dear Sir: In a communication which I received from you a few days since, you requested me to furnish you with an article on the cultivation and manufacture of sugar. I have had some hesitancy in complying with your request, only from the fact that my opinions would possibly differ with some of the farmers of the country, and some, too, of experience. But, after giving the subject due consideration, and thinking I might be of service to some in my communication, I have yielded to your request; and, so far as I am capable of giving my opinions, you shall have them freely. As I am more accustomed to using my farming utensils than wielding the pen, and knowing better how to make sugar than to describe the operation, you must allow me to give my opinions in my own plain way. In the first place, I prefer the ribbon cane for this climate, for the reason that it will stand the cold spells, which we are sometimes subject to in the fall season, much better than the green. I have noticed in some crops that I have made, where my cane has been mixed, that the green cane has soured after a killing frost, when the ribbon cane would be perfectly sweet. This I consider a great advantage, by giving the planter more time to gather in the other products of his farm. The sample of sugar which I send you was made from the ribbon cane after a severe freeze, which I consider a good test of its preference. I have been accustomed to banking my seed cane in low, flat beds, say about four feet deep, with the roots inclined downwards, and leaving them entirely uncovered with earth until after the first frost, or until the blades are entirely dry. The advantage to be gained by this mode of putting up seed cane I consider a great one, from the fact that the cane will remain in a warm, moist state during the winter, and the roots and eyes will not only be perfectly sound by the usual planting time, but will have put forth their sprouts, and secure to the planter an earlier and better stand. The usual mode of banking up seed, by drawing the bed to a narrow ridge on top and covering with earth before the blades are thoroughly dried, causes the cane to heat, and consequently a great many of the sprouts will perish from dry rot.

The kind of soil from which I raised my cane last year is of good quality pine land, about fourteen or fifteen inches deep, of a very light cast, and has been in cultivation several years. Cane should never be planted on first year's ground, from the fact that the juice extracted from it will not granulate. The most favorable time for planting, in my opinion, is

about the middle of February, provided there is a suitable warm spell ; for I consider the cane to be doing much better by remaining in bank, where it will sprout and remain sound, and not exposed to the cold until the earth has become a little warm. My own observation has convinced me that cane planted about this time will grow off faster, be equally as forward, and the stand much better, than when planted earlier. I have usually planted my cane four feet between rows, and very thick in the drill ; a stalk of cane six feet long should lap or be touching. The seed should be planted deep, and covered with a turning plough.

The first working which it receives should be done with the hoe—what is commonly called by the farmers "flat weeding." This will break the crust which may have been formed on the surface of the bed, and forward its coming up. The first ploughing I usually give my cane is with the turning plough ; but after it becomes of any size, I use the sweep. The usual time for laying by is the first of June ; but should it be growing rapidly, I would advise later and deeper ploughing, which will check the growth and cause it to mature better.

It will have been noticed by all who are in the habit of using it, that the saccharine matter is greatly increased after the growth has been checked by the first frost, and until then should never be cut for grinding. I am convinced that a great many of the failures in making sugar are caused from the fact of the cane being topped too high, and consequently a good deal of the juice is extracted from cane that is not matured. The best criterion to be governed by is from the blades drying up, and leaving the stalk exposed only so far as the cane is matured ; and I make it a rule to cut my cane at the joint above the first green blade, by which means you are certain not to have any cane unmatured. I have found a great advantage in cutting my cane and exposing it to the sun about two or three days before grinding. A good deal of the watery particles will evaporate, without any loss of the saccharine matter. The process of boiling will depend a great deal upon the quality of the cane and its maturity. A person would learn more from seeing a few boilings taken off than from all he might hear or read on the subject. In the first place, I would advise the use of lime, which assists a great deal in clarifying, and causes the grain to be much firmer. My plan of using is to mix a half gallon of the cane juice with a half pint of lime ; after setting a while, pour it off. This quantity should be put into a hundred gallons of the cane-juice. It is best not to commence skimming until it is nearly in the act of boiling, at which time most of the scum has risen to the surface, and is much easier taken off. There are so many marks by which the sugar-maker ascertains when his boiling has arrived at the sugar state, that it would be difficult to describe them all. I will give one or two which I consider most certain. It is known by all who have any experience in sugar-making, that as the boiling approaches the sugar state the froth or foam is greatly increased, and the bubbles become much smaller, by constantly dipping up and pouring it off from the cooler. It will be seen that the quantity of liquor or sirup decreases very rapidly after the boiling has turned down ; this should be continued until there is but a small quantity of sirup left, which will be seen in the drainings from the cooler. Another criterion to be governed by, is, when it is ready to be taken off, the bubbles, instead of rising and falling out from the centre, will turn in ; when it should be taken off and put into the cooling vessel as soon as possible.

With regard to the process of dripping, I would say that it is all important to have the molasses well drained from the bottom of the barrels; to effect which, it is necessary to have two or three holes bored in the bottom, into which should be inserted stalks of cane, which will gradually wither and leave the orifice larger at the time when the draining is most needed from the bottom. The hoops should be well loosened after the sugar has been in the barrels a few days.

In conclusion, I would say that I believe as good sugar can be raised here as in any country, from the fact that I have seen samples of sugar made in this country that would compare with the best quality of imported sugar; and, if not cultivated as an article for market, should be made by all the farmers for their own consumption.

Yours, truly,

FRANCIS P. MILLER.

Gov. Wm. D. Moseley.

Consulate of the United States,
Singapore, *December* 17, 1844.

Sir: I am indebted to the kindness of my excellent friend, Francis Markoe, esq., of the Department of State, for a copy of your report on patents, to Congress, at the early part of the present year, which I consider a most valuable work, calculated, as it is, to circulate precious information to the great mass of our people without any expense. As, besides notices of patents, you have embodied useful notes from many experienced persons, I have thought that some account of the Chinese manner of sugar-cane cultivation might be agreeable to you; and, should I be correct in this supposition, you are at liberty to make any use you may think proper of it.

The cane is topped off in the usual manner with us, and the upper end is lopped off until cut quite into the solid part, when the heart or pith of it is yellowish and substantial, in order to produce lateral shoots, and prevent sprouting at the end; the lower leaves are then removed; and, if the tops are gathered on the day of cutting, they are allowed to remain over night in the open field, that the sugary sap may somewhat dry up, and be pervious to the water into which they and others, previously cut, are put to soak for twenty-four hours. This process, they say, prevents destructive insects being engendered. After twenty-four hours soaking in water, the plants, which, for the convenience of handling them, are tied up with cane leaves into bundles of about thirty plants, are laid, standing upright and compactly pressed against one another, in a square hole, about six inches deep, and of any given size; when quite full, the mould at the four sides is raised up to near the height of the mass, and muddy water is then thrown on the top till quite drenched; a layer of cane leaves, mixed with dirt, is now spread on to prevent sudden evaporation of the water. For four or six succeeding days considerable quantities of water are thrown on, but without disturbing the top layer. At the end of that time the top and sides are removed, and the eyes of the cane plants are seen to have sprouted out one-half to a full inch, and they are now carried in baskets to the furrows prepared to receive them. By this treatment not a single

plant is lost, and they are as far advanced as those plants which have been otherwise planted full three weeks before.

Their mode of planting is as deserving of attention, and is thus: their furrows are hardly four inches deep, and in the *afternoons* only they plant into earth made quite fine by being well worked. The prepared plants are carefully laid almost flat, the lower ends only dipping in the ground, leaving the young shoots quite unburied; when, in a week or two, the new plants are observed to shoot up with great vigor. Manure, which has been plentifully prepared by burning the dried cane leaves and weeds gathered in hillocks in various parts of the field, mixed with mould, which is burnt with them, is laid in small quantities on the *buried end*, and not on the whole plant; about a double handful of this manure is laid on each. It is carried very readily in baskets, which are slung to a pole or staff, in the Chinese manner of carrying burdens, across the shoulders, which is familiar to most persons who have seen Chinese prints; and it is wonderful to see the effect produced in a few days: they prefer to lay it on in dry weather. When the plants are a month or six weeks old, and the weather likewise dry, liquid manure, composed of the discharges of the body, the washings of pig-sties, indeed all the odds and ends about the house, (which are carefully collected in tanks,) is carried in the like manner, in pails, and ladled out in small quantities on the young canes. A month later they require weeding, and perhaps burnt manure, a second time; and they are finally moulded and shoed. Owing probably to the usual dampness of this climate, they begin early to strip the canes, and never allow the dead leaves to remain. These are gathered and burnt to manure, as before said. Thus each field is made to provide itself with a plentiful supply of that (to them) indispensable article; for they never allow their ground to remain fallow, nor do they practise rotation of crops. But, by following this simple mode, their plantations far exceed in luxuriance and abundance of canes any thing I ever saw in the whole range of the West Indies, beginning with Barbadoes, down to the fertile plain extending along the whole southern coast of Porto Rico. There are never less than fifteen large Tahiti canes in the stoles, and even thirty. Some skill and considerable practice are required to make the burnt manure good in their estimation; for, unless it be quite black, they think little of it. To effect this, some pieces of stray wood are piled up, set on fire, and then grass or cane-leaves, partly dry, are laid on—then a little earth; as this slowly consumes, some ten or twelve hours later an opening is made at the base of the hillock, and more grass, leaves, and mould are laid on the red-hot ashes, and the pile is made again to assume a conical form; and so on, for a day or two, until a sufficiently large mass of manure is provided, to be at hand when wanted; nor is their process a slow one, as might be imagined; for, although the planted canes are ripe in thirteen months, here, under the equator, one coolee, or laborer, raises two and a half acres of canes. The ratoons ripen in ten months; these are slightly manured with burnt manure. The hoe is their only implement. I have often paused in wonder on seeing the most luxuriant fields standing in sandy ground, apparently without a particle of soil, and made to grow thus by the process above indicated.

The business of growing and manipulating are separate among the Chinese. Here contracts are made by the sugar-mill owners, with the cane-growers, to convey their canes to the mill, manipulate them into

sugar, and pay them at rates varying from one to one and a half Spanish dollars per picul ($133\frac{1}{3}$ pounds English) of sugar in the raw state; that is, with the molasses included made therefrom; the grower receiving a monthly advance of two Spanish dollars for his support, which is retained, with interest, at one per cent. a month, from the proceeds of the sugar made from his canes. The ground may belong to either party, without in any way affecting the contract; but, generally, it belongs to the mill owner. This latter furnishes the means of conveyance. All the implements for manufacture, and the laborers in and about the sugar house, are at his own expense; which is not excessive, as a first-rate boiler (Chinese) is hired for from eight to ten dollars per month, and other laborers, of the same nation, at from three to four dollars, and found in nothing. In fact, all servants are paid wages, and are not found.

The process of boiling is after that of the West Indies, as all the works are carried on by Europeans. But, instead of our copper skimmers, may be seen occasionally, as a substitute, a sort of sieve, with a long handle, and ladles, made in a conical form, from the bark of a palm, sago, or cocoanut tree, which appears to answer their purpose quite as well as the most expensive copper ones. Their manner of putting the sugar from the cooler, quite liquid and hot, into bastard moulds, as the refiners with us call their large earthen moulds, is, I think, a far preferable mode than, as in the West Indies, to allow the sugar to crystallize in the cooler, and put it into large hogsheads on the following morning. The Chinese make much less molasses, and the sugar has a larger and brighter grain, by their process. Two strikes are usually run into the cooler, when, on being stirred two or three times, it is allowed to crystallize, which it does in a very short time; and the next day but one, when quite cool, the cones are reversed on a table, the cane stoppers or corks are removed, a small quantity of water is poured into the vent, now open, to facilitate the separation, and, in a minute afterwards, the cone or mould is lifted up, leaving a perfect loaf of hard sugar, which is broken up, and carried and put in draining cases, under which are laid troughs, which convey the molasses into vessels disposed at their lower end to receive it.

The Chinese are said to be a people without *genius*, and I am strongly inclined to that opinion; but, instead of flights of fancy, or of the imagination, they have that which *works* quite as well—a great deal of shrewdness and observation, based on good sense; and we have much to learn from them.

I shall be very happy to receive future numbers of your valuable reports, through the friend I have before indicated, and, indeed, as many papers on southern agriculture as you may wish to get rid of; for much of my time and attention are given to that subject. If I can be agreeable to you in any way, in this distant country, I pray you to indicate the manner, and command me. I think we have met formerly; but time and distance, as they increase, obliterate much of our earlier recollections.

I have the honor to be, sir, your most obedient servant,

J. BALESTIER.

Hon. H. L. Ellsworth,
Commissioner Patent Office, Washington.

MAPLE SUGAR—A NEW ELEMENT.

To the Editor of the Tribune:—We are just through our annual sugar season, and all feel satisfied. The crop is large, very large—more than in any year for some time. Every farmer has enough, and many have made one, two, or three tons.

Arrangements have been made to give more particular statistics of the amount. It is becoming of great importance to the State, and more interest is taken in improving the quality. But my object at this time is merely to call the attention of scientific men to the nature of a substance found in the sugar. The sugar-makers have always noticed that a kind of *grit* settles in the sugar and molasses after it is made. This varies greatly in quantity in different years. The present year the quantity is large. When the sugar was manufactured chiefly in the woods, it was supposed to be ashes or dirt, deposited during the process of evaporation; but the quantity is the same when the sap is evaporated in the house, and cleansed with the greatest care. From a small quantity (perhaps 50 lbs.) I obtained nearly a gill of this substance. When tasted with the sugar, it simply appears like sand; but upon dissolving the sugar, and repeatedly washing it with water, I obtained a substance nearly white, and with a *very pungent, alkaline taste.*

The presence of ammonia in sugar is mentioned by Liebig and Johnston, in their works upon agricultural chemistry; but, if I understand their remarks upon the subject, they refer only to a gas which arises during the process of evaporation. But here is a tangible salt, and of sufficient quantity to be of some interest.

Will some one, through your paper, give an account of the nature of the substance, and thus satisfy the curiosity of many of your readers, and perhaps add a new fact to the researches of science?

WINDSOR CO., VERMONT, *April*, 1845.

MAPLE SUGAR.

As most persons who have not informed themselves on the subject imagine that we are indebted to cane sugar for our main supply, and that maple sugar is a petty neighborhood matter, not worth the figures employed to represent it, we propose to spend some space in stating the truth on this matter. We will exhibit, 1st, the amount produced; 2d, the proper way of manufacturing it; 3d, the proper treatment of the sugar-tree groves.

We shall confine our statistics to the most important northern and western States.

1. New York produces annually	10,048,109 lbs.
2. Ohio	6,363,386 "
3. Vermont	4,647,934 "
4. Indiana	3,727,795 "
5. Pennsylvania	2,265,755 "
6. New Hampshire	1,162,368 "
7. Virginia	1,541,833 "

8. Kentucky - - - - - -	1,377,835 lbs.
9. Michigan - - - - - -	1,329,784 "
Total of nine States -	22,464,799
Residue thus: Add for Maine, Massachusetts, Connecticut, Maryland, Tennessee, Illinois, Iowa, Missouri, and Wisconsin - - - - -	2,030,853
	24,495,652 lbs.

Something should be subtracted for beet root and cornstalk sugar. But, on the other hand, the statistics are so much below the truth on maple sugar, that the deficiency may be set off against beet root and cornstalk sugar. That the figures do not more than represent the amount of *maple sugar* produced in these States, may be presumed from one case. Indiana is set down at 3,727,795 lbs.; but in the four counties of Washington, Warrick, Posey, and Harrison, no account seems to have been taken of this article. In Marion county, four of the first sugar-making townships, Warren, Lawrence, Centre, and Franklin, are not reckoned. If we suppose these four townships to average as much as the others in Marion county, they produced 77,648 lbs.; and instead of putting Marion county down at 97,064 lbs., it should be 174,712 lbs. It is apparent, from this case, that in Indiana the estimate is far below the truth; and if it is half as much so in the other eight States enumerated,* then 22,464,799 lbs. is not more than a fair expression of the *maple sugar* alone.

Louisiana is the first sugar growing State in the Union. Her produce, by the statistics of 1840, was 119,947,720, or nearly 120,000,000 lbs. The States of Mississippi, Alabama, Georgia, South Carolina, and Florida, together, add only 645,281 lbs. more.

Cane sugar in the United States - - -	120,593,001 lbs.
Maple sugar in the United States - - -	24,495,652 "

Thus about one-sixth of the sugar made annually in the United States is made from the maple tree.† It is to be remembered, too, that in Lou-

---

* Dr. J. C. Jackson puts Vermont at 6,000,000 lbs. per annum, while the census only gives about 4,000,000.

† The data of these calculations, it must be confessed, are *very* uncertain; and conclusions drawn from them as to the relative amounts of sugar produced in different States are to be regarded, at the very best, as problematical. We extract the following remarks from an article in the Western Literary Journal, from the pen of Charles Cist, an able statistical writer:

"It is not my purpose to go into an extended notice of the errors in the statistics connected with the census of 1840. A few examples will serve to show their character and extent. In the article of hemp, Ohio is stated to produce 9,080 tons, and Indiana 8,605 tons, either equal nearly to the product of Kentucky, which is reported at 9,992 tons, and almost equal, when united, to Missouri, to which 18 010 tons are given as the aggregate. Virginia is stated to raise 25,594 tons, almost equal to both Kentucky and Missouri, which are given as above at 28,002 tons. Now the indisputable fact is, that Kentucky and Missouri produce more hemp than all the rest of the United States, and ten times as much as either Ohio, Indiana, or Virginia, which three States are made to raise 50 per centum more than those two great hemp-producing States.

"The sugar of Louisiana is given at 119,947,720 lbs., equal to 120,000 hhds.; 160 per cent. more than has been published in New Orleans as the highest product of the five consecutive years, including and preceding 1840.

"But what is this to the wholesale figure-dealing which returns 3,160,949 tons of hay as the product of New York for that article—a quantity sufficient to winter all the horses and mules in the United States!

"Other errors of great magnitude might be pointed out; such as making the tobacco product of Virginia 11,000 hhds., when her inspection records show 55,000 hhds. thrown into market as the

isiana it is *the* staple, while at the north maple sugar has never been manufactured with any considerable skill, or regarded as a regular crop, but only a temporary device of economy. Now it only needs to be understood that maple sugar may be made so as to have the flavor of the best cane sugar, and that it may, at a trifling expense, be refined to white sugar, and the manufacture of it will become more general, more skilful, and may, in a little time, entirely supersede the necessity of importing cane sugar. Indiana stands fourth in the rank of maple sugar-making States. Her annual product is at least *four million pounds*, which, at 6 cents a pound, amounts to $160,000 per annum. A little exertion would quickly run up the annual value of our home-made sugar to half a million of dollars.

Maple sugar now only brings about two thirds the price of New Orleans. The fault is in the manufacturing of it. The saccharine principle of the *cane and tree are exactly the same.* If the same care were employed in their manufacture, they would be undistinguishable, and maple sugar would be as saleable as New Orleans, and, if afforded at a less price, might supplant it in the market. The average quantity of sugar consumed in England by each individual is about 30 lbs. per annum. Marion county contains about 20,000 inhabitants. At 30 lbs. per head, the sugar consumed annually is not less than 600,000 lbs., and for the whole State 24,000,000 lbs., reckoning the population at 800,000. There is annually produced in this county about 175,000 lbs. of sugar; leaving about 425,000 lbs. to be purchased, which, at an average of *five* cents per lb., amounts for this single county to $21,250, a sum well worth saving, and, by a little attention to the making of domestic sugar, very easily saved.

II. MAPLE SUGAR MAKING.

1. Greater care must be taken in collecting the sap. Old and half decayed wooden troughs, with a liberal infusion of leaves, dirt, &c., impart great impurity to the water. Rain-water, decayed vegetable matter, &c., add *chemical* ingredients to the sap, is troublesome to extract, and injures the quality if not removed. The expense of clean vessels may be a little more, but with care it could be more than made up in the quality of the sugar. Many are now using earthen crocks. These are cheap, easily cleaned, and every way desirable, with the single exception of breakage. But if wooden troughs are used, let them be kept scrupulously clean.

2. The kettles should be scoured thoroughly before use, and kept constantly clean. If rusty, or foul, or coated with burnt sugar, neither the color nor flavor can be perfect. Vinegar and sand have been used by experienced sugar-makers to scour the kettles with. It is best to have at least three to a range.

All vegetable juices contain *acids*, and acids resist the process of crystallization.

---

crop of that year. Who believes that 12,233 lbs. of pitch, rosin, and turpentine, or the tenth part of that quantity, were manufactured in Louisiana in 1840, or that New York produced 10,093,991 lbs. of maple sugar in a single year, or twenty such statements equally absurd, which I might take from the returns?"

Mr. Cist will find, in the appendix to Dr. Jackson's Final Report on the Geology of New Hampshire, a statement that Vermont makes 6,000,000 lbs. of sugar annually. If this be so, we may, without extravagance, suppose that New York reaches 10,000,000 lbs. So far as we have collateral means of judging, the amount of maple sugar is *under*-stated in the census of 1840.

Dr. J. C. Jackson* directs one *measured ounce* (one-fourth of a gill) of pure lime-water to be added to every gallon of sap. This neutralizes the acid, and not only facilitates the granulation, but gives sugar in a free state, now too generally acid and deliquescent, besides being charged with salts of the oxide of iron, insomuch that it ordinarily strikes a black color with tea.

The process of making a pure white sugar is simple and unexpensive. The lime added to the sap, combining with the peculiar acid of the maple, forms a neutral salt; this salt is found to be easily soluble in alcohol. Dr. Jackson recommends the following process: Procure sheet-iron *cones*, with an aperture at the small end or apex; let it be coated with white lead and boiled linseed oil, and thoroughly dried, so that no part can come off. [We do not know why earthen cones, unglazed and painted, would not answer equally well, besides being much cheaper.] Let the sugar be put into these cones, stopping the hole in the lower end until it is entirely cool. Then remove the stopper, and pour upon the base a quantity of strong whiskey or fourth-proof rum;† allow this to filtrate through until the sugar is white. When the loaf is dried it will be pure white sugar, with the exception of the alcohol. To get rid of this, dissolve the sugar in pure boiling hot water, and let it evaporate until it is dense enough to crystallize. Then put it again into the cone moulds and let it harden. The dribblets which come away from the cone while the whiskey is draining may be used for making vinegar. It is sometimes the case that whiskey would, if freely used in a sugar camp, go off in a wrong direction, benefiting neither the sugar nor the sugar-maker. If, on this account, any prefer another mode, let them make a *saturated* solution of loaf sugar, and pour it, in place of the whiskey, upon the base of the cones. Although the sugar will not be quite as white, the *drainings* will form an excellent molasses, whereas the drainings by the former method are good only for vinegar.

III. CARE OF SUGAR ORCHARDS.

It is grievous to witness the waste committed upon valuable groves of sugar trees. If the special object was to destroy them, it could hardly be better reached than by the methods now employed. The holes are carelessly made, and often the abominable practice is seen of cutting channels in the tree with an axe. The man who will murder his trees in this tomahawk and scalping-knife manner, is just the man that Æsop meant when he made the fable of a fellow who killed his goose to get at once all the golden eggs. With good care, and allowing them occasionally a year of rest, a sugar grove may last for centuries.

1. As soon as possible get your sugar grove laid down to grass, clear out under-brush, thin out timber and useless trees. Trees in open land make about *six pounds* of sugar, and forest trees only about *four* pounds, to the season. As the maple is peculiarly rich in potash, (four fifths of potash exported is made from sugar maple,) it is evident that it requires

---

* Appendix to Final Report on the Geology and Mineralogy of New Hampshire, page 361. This admirable report is an able exposition of the benefit of public State surveys.

† If those who drink whiskey would pour it on the sugar in the refining cones, instead of upon sugar in tumblers, it would refine *them* as much as it does the sugar, performing two valuable processes at once.

that substance in the soil. Upon this account we should advise a liberal use of wood ashes upon the soil of sugar groves.

2. *Tapping trees.*—Two taps are usually enough—never more than three; for though as many as 24 have been inserted at once without killing the tree, regard ought to be had to the use of the tree through a long series of years. At first, bore about two inches; after ten or twelve days remove the tap, and go one or two inches deeper. By this method more sap will be obtained than by going down to the colored wood at first. I state, upon the authority of Wm. Tripure, a Shaker, of Canterbury, N. H., that about 7 lbs. of sugar may be made from a barrel of 20 gallons, or 4 lbs. the tree for forest trees; and two men and one boy will tend a thousand trees, making 4,000 lbs. of sugar.

3. We would recommend the setting of pasture lands and roadsides of the farm with sugar maple trees. Their growth is rapid, and no tree combines more valuable properties. It is a beautiful shade tree; it is excellent for fuel; it is much used for manufacturing purposes; its ashes are valuable for potash, and its sap is rich in sugar. There are 27 species of the maple known; 12 of them are indigenous to this continent. All of these have a saccharine sap, but only two to a degree sufficient for practical purposes, viz: *acer saccharinum*, or the common sugar maple, and *acer nigrum*, or the *black* sugar maple. The sap of these contains about half as much sugar as the juice of the sugar-cane. One gallon of pasture maple sap contains, on an average, 3,451 grains of sugar; and one gallon of cane-juice, (in Jamaica,) on an average, yields 7,000 grains of sugar.

But the cane is subject to the necessity of annual and careful cultivation, and its manufacture is comparatively expensive and difficult. Whereas the maple is a permanent tree; requires no cultivation; may be raised on the borders of farms without taking up ground, and its sap is easily convertible into sugar, and, if carefully made, into sugar as good as cane sugar can be. Add to the above considerations that the sugar-making period with us is a time of comparative leisure with the farmer, and the motives for attention to this subject of domestic sugar-making seem to be complete.

From the Cultivator.

MAKING SUGAR FROM CORNSTALKS.

A short time since, I met with Mr. Adams's account of his experiment in manufacturing cornstalk sugar, undertaken from the inducements offered by the New York State Agricultural Society, and for which they awarded him a premium of one hundred dollars. I was much interested in its perusal, as it strongly reminded me of the difficulties and discouragements experienced in the earlier stages of the same inquiry, when experiment was the only available source of knowledge to which we could turn for assistance in our exertions. As I have pursued this subject with unabated confidence and reasonable success, since its commencement, my experience may perhaps be useful to Mr. Adams and others engaged in perfecting this important and interesting manufacture.

Before proceeding further, I must find a little fault with your agricultu-

ral society. Its premium was offered for the "maximum quantity of sugar made from an acre of northern corn." It appears to me that the great object to attain is a plan by which sugar may be made *profitably.* It is very possible to expend more labor in the manufacture than the article would be worth; such a plan would of course be worthless practically, whatever might be the *amount* produced. Secondly, in planting corn for sugar, I should prefer seed that had ripened in a more southern latitude, as less liable to run to ear early in the season. In raising this crop, the great end to secure is the perfect growth of the plant in every particular, except in the formation of its seed. No plan ever yet tried has succeeded completely in effecting this object. Those stalks which, from some cause yet unknown, have shown no disposition to form grain, are always far more juicy, and yield a much larger quantity of sugar than those from which the ear has been removed. As soon as this hitherto accidental condition of the plant is brought, by persevering efforts, within our control, I confidently expect that the cornstalk will not merely rival but exceed the sugar-cane in the amount of saccharine matter it will yield. The past season, a small lot of corn was planted in rows, three feet apart, and about six inches asunder in the row. As soon as the tassels appeared they were pulled out. The result of this experiment was encouraging, but not entirely satisfactory; another lot of corn, growing within one hundred yards, was allowed to tassel, and this perhaps caused the partial failure. In order to try this plan fairly, the corn should be grown distant from any other, and the tassels pulled out before any of their pollen has been shed. Very thick planting, in order to prevent earing, is objectionable, as it renders the crop more liable to be prostrated by storms; and the stalks being small, the labor of handling them is increased: they should not be less than one inch in diameter, or about the size of broom handles; the distances in planting, in order to produce this size, will vary according to the quality of the soil. Whatever plan is adopted to prevent earing, it must be attended to, or the sugar of the stalk will be expended in the formation of grain.

When the corn is ripe—which will happen about the usual time of cutting corn—cut off the tops at the point where the ear generally forms; the leaves on the stalk below this are few in number and mostly dead; they may be sufficiently removed by simply passing the knife from top to bottom on each side of the stalk. By pursuing this plan, the formidable labor of stripping the stalks, which has been complained of, is greatly lessened, and the whole business put in a practicable shape.

The method of curing "tops and blades" is so well understood by farmers, that nothing need be said about it here. Experience has proved that the extras of this crop—the tops, blades, crushed stalks, &c.—are worth more, when properly secured, than the whole labor required in growing and manufacturing, provided this labor is economised in the way pointed out. In the list of plants cultivated for forage, there is not in the whole world another one that is equal to this in the amount of nutriment which it contains. It is well worth cultivating for the fodder alone; the stalks therefore cost nothing. Every farmer may see, from this, (if he chooses) how to steer clear from his grocery bill.

The mill for grinding, best suited for the farmer, is a simple one, and need not cost more than $10.

The boiling apparatus should consist, first, of two defecating kettles;

they may be of cast iron, and capable of holding as much juice as the mill will press out in fifteen or twenty minutes; these kettles must be placed so that a quick and strong fire can be made under them, and so arranged that they can be emptied at a moment's warning. Second: two or three evaporating pans; a single sheet of Russia iron, bent up six inches at the sides and ends, and riveted, makes an excellent pan of this description. Third: two copper or tin pans for finishing; these should be flat bottomed, six inches deep, and so arranged that they can be removed from the fire instantly when the charge is finished. They should never have much over two inches in depth of sirup placed in them at one time, and should each be of such a size that a charge of three or four gallons will not fill it deeper than this.

The difficulty of manufacturing sugar to the *best advantage* has always been considerable. This has grown out of the foreign substances always found connected with it in the juices of plants. Sugar is one of the most easily decomposed substances in nature. The juice of a plant may be very rich in sugar, yet, when slowly evaporated, the residue will not show a single trace of saccharine. In the process of vegetation, as the plant approaches maturity, sugar is changed into starch. In the germination of the seed a contrary change occurs, and starch is converted into sugar. I took a portion of sprouted corn and macerated it in water until the sugar was extracted; the liquid then strikingly resembled, both in taste and smell, the juice of cornstalk after it had been clarified; it was then set to evaporate over a slow fire; it gradually grew darker in color, and in a short time it appeared very much like beet-juice. Before the evaporation was finished every particle of sugar had disappeared, and, from being sweet and pleasant to the taste, it had become black, bitter, and nauseous. The same experiment was repeated under the same circumstances, except that a small portion of starch was added to the water; in this case the sugar was not decomposed, but retained its distinctive qualities throughout evaporation. The chemical reasons for this it is needless now to discuss; the simple fact, and its application, are sufficient for our purpose. Wheat flour consists principally of starch, and was used with good success, though perhaps pure starch would be better. One pint of flour was mixed with two gallons of skim-milk, and one pint of this mixture was added to thirty gallons of juice. These proportions are not given as best, for many more experiments will be necessary before they can be determined accurately.

As the juice comes from the mill, it should run into a receiver which will hold just enough to fill one of the defecating kettles; while in this receiver the mixture of flour and milk, and also the necessary quantity of lime water, must be added and well stirred in. It is then poured at once into the defecating kettle and heat applied; a very firm thick scum is by this means separated, and the juice becomes clear; it is next run through a flannel strainer into one of the evaporating pans, and the boiling kept up briskly. Take a shovelful of red-hot coals from the furnace, and, after blowing the ashes off, throw them into the pan; as you put in more juice, add more coal; as the pan becomes filled with coal, take out that which has been in longest. From this pan the juice is run in succession through the others, (straining it when convenient,) until it is finished.

WM. WEBB.

Wilmington, Del., *March* 14, 1845.

From the Cultivator.

CORNSTALK SUGAR AND MOLASSES.

Mr. Tucker: An opportunity offering, I am induced to send you samples of sugar and molasses from the juice of cornstalks. It is now about seven weeks since this was pressed and boiled. You will perceive that granulation and drainage are tolerably perfect. 688 pounds of the crystallizable sirup was made from one measured acre; and, had it not been for some loss sustained at the first boiling, I believe the amount would have been 700 pounds. Over 100 pounds per day were made at four successive boilings.

I believe it is in the power of any farmer to make abundance of sugar and molasses for his own use. The apparatus is simple, and within the reach of almost every one; all that is needed is a mill to crush the stalks and express the juice, and three common iron kettles, set in a brick arch, for boiling. Neither is there any mystery or difficulty in the process but what a little experience would enable any one to overcome. The principal things to be attended to in the boiling are, to be careful to skim, and get the juice well clarified before it comes to a boil; some milk and flour, as recommended by Mr. Webb in your July number for 1845, facilitates this very much. Some *clear* lime-water is also necessary. We have found that using the cream of lime, or the lime mixed up in the water, prevents the fecculent particles from coming to the surface, and makes it necessary to strain, and occasions much trouble and loss; on the contrary, the *clear* lime-water does not have this effect.

It is also necessary to boil as rapidly as possible; the quality of the article and the crystallization depend altogether on this; and, lastly, it is necessary to know when it is boiled sufficiently to granulate. We have this year boiled without a thermometer, and found no difficulty, by attending to the directions given in statements formerly published and republished in the reports of the Commissioner of Patents.

One of my neighbors has erected a mill, &c., and is at this time engaged in boiling. I believe he will fail to make sugar, but is making a satisfactory article in the way of molasses, and I have no doubt will succeed another year.

Yours respectfully,

JOHN BEAL.

New Harmony, Ia., *October* 14, 1845.

New Harmony, Ia., *December* 22, 1845.

Dear Sir: Yours of the 3d instant reached me by the last mail. I cheerfully comply with your request to furnish you with a statement of my this year's experiment in the growth and manufacture of cornstalk sugar; also, a sample of the sugar. This year's experiment has been still more successful than the last in the quantity per acre, and, I believe, some little improvement in the quality. I planted a measured acre, and the yield was 688 pounds of the crystallizable sirup; and had it not been for some loss sustained at the commencement in trying some new experiments that were unsuccessful, it would have reached 700 pounds. The continued culture of corn for this purpose is now a settled point with me, being well satisfied that it is *here* equally profitable with anything else grown in general. I say in general, for there may be some years when particular articles may be an exception.

In consequence of this opinion, I endeavored, in my last communication to the late Commissioner, to institute a comparison as to the expense of raising corn and sugar. From some errors, either typographical or original, that statement was altogether incorrect, which I will endeavor to correct in the present communication, although, owing to the present high price of corn, it will not contrast so favorably for the sugar. I think it is a fair estimate to value this sirup at 5 cents per pound, seeing that sugar ranges here from 8 to 12 cents, and molasses from 40 to 50 cents per gallon. The cultivation of each, up to the time of pulling of the ears, is the same; the pulling of the ears I offset by the pulling of the corn.

688 pounds of sirup, at 5 cents - - -		$34 40
Deduct, for blading, cutting, and getting stalks to mill,		
1 man, 8 days, at 50 cents per day - - -	$4 00	
Horse, hauling the same 2 days, at 25 cents per day -	50	
Grinding, man and horse 8 days, at 75 cents per day -	6 00	
Boiling, 8 days, at 50 cents per day - - -	4 00	
Fuel - - - - - - -	2 00	
Interest and repairs on fixtures - - -	3 00	
		19 50
Net value of sirup - - - -		14 90
Corn, 50 bushels, at 25 cents per bushel - -	12 50	
Deduct for husking - - - - -	1 00	
Net value of corn - - - -		11 50
Balance in favor of sugar - - -		$3 40

By a reference to the statement of Mr. Tillotson, in the report of the Commissioner for 1843, it will be seen how much the expense may be reduced on a large scale.

It will also be seen by Mr. K.'s statement that his product was 200 gallons of the sirup for the 4 acres, or 50 gallons per acre. By dividing 688 by 12 pounds, (the weight of a gallon of sirup,) it will be seen that my yield was over 57 gallons per acre.

I am by no means satisfied with the drainage. The molasses, though clear and not so high colored as ordinary molasses, is still much thicker, and will not flow freely from the sugar. It generally comes cool weather within a few weeks after the boiling; this is much against the drainage. If it could be kept in a temperature of from 70 to 80 degrees, I think the process would be much accelerated.

A small quantity (about 6 or 7 gallons) was put into a tapering vessel by itself; this was drained in a few weeks, and during the continuance of the warm weather, and the sugar was of better quality than usual. The sugar sent you was from this drainage, but from the bottom of the vessel; therefore, not as fair as the upper portion. Some sugar and molasses have been sent to the editor of the Albany Cultivator, some notice of which has probably been given in the December number of that excellent periodical.

Respectfully yours,

JOHN BEAL.

Hon. Edmund Burke.

APPENDIX No. 14.

From the Cultivator.

CULTURE OF CARROTS AND ONIONS.

Mr. Editor: Having had good success in raising carrots, onions, &c., I have had a desire to make my mode of raising such vegetables public, as it differs in some respects from the modes usually practised in this country. But when I considered I was not well skilled in writing articles for publication, I was led to hesitate, until I reflected that language—the vehicle by which our ideas are communicated—may be compared to the carriage which conveys the produce of the farmer to market; and when I remembered that it matters little whether the carriage is constructed with two, three, four, or even five wheels, so long as the produce is easily, expeditiously, and safely conveyed, it gave me some more confidence. And then, again, I received additional encouragement by some remarks of a correspondent of the Albany Cultivator, who, after speaking of the reading of agricultural papers, says: "This reading gives an opportunity of becoming acquainted with the practical experience of farmers. It is much to be desired that more of this class of farmers could be induced to give their views. There is too frequently a reluctance to writing. This reluctance should be overcome. It is not expected that plain farmers should always frame sentences in the style of *literary* writers, nor is this necessary—give us the *facts* in an intelligible manner." And so I am encouraged to proceed. And to commence, I will state the amount of carrots and onions I obtained, and then some of the means used to obtain so large crops. But, before proceeding, I will remark that I have no doubt that in several respects my mode of management may be improved upon.

Of carrots, I had at the rate of twelve hundred and nine and a half bushels to the acre, large measure, and of onions six hundred and thirty bushels.

The land on which these crops grew—being of a full middling quality as to richness—was ploughed early in the spring, at a time when the ground was in a sufficiently dry* state to pulverize. It was then harrowed several times over; then ploughed a second time, in such a manner as to have no treading of the team upon it. A row of boards to stand upon while sowing the seed was laid down on one side of the ground about to be sowed. With a common hay rake, six or seven feet in breadth was soon made sufficiently level to sow. A line, fastened to two stakes, was stretched to mark the place where the first row was to be sowed. Then, with a common garden hoe, a place near one inch deep was made for the seeds. The onion seeds were then sowed very evenly and expeditiously, with a contrivance which I will hereafter describe, and covered with the hoe. Then the line was moved fifteen inches to mark out the place for the second row. The boards were then moved over the row that had been sowed, so that

---

* As there is often too much moisture in land to plough it early in the spring, and as carrots, onions, and parsnips need to be sowed early, it would doubtless, in many cases, be well to ridge the land up in the fall.

the second row could be dug out, sowed, and covered, as was the first. The line was then moved to mark the third row, and the boards were also moved over the second one, which was already sowed. In this manner I proceeded until the whole was finished, and the ground presented a beautiful level and mellow appearance, as if a light roller had passed over it, without having the appearance of being trodden down, as is often the case where men walk upon the ground. The carrots were sowed in much the same manner as the onions, with the exception that eighteen inches space was allowed for the rows, instead of fifteen. A small quantity of plaster was sowed with the seeds.

When the carrots and onions were up sufficiently high to hoe, I commenced at one end of the rows, and hoed in as far as I could conveniently reach. Two pieces of board, each near three feet long and ten inches wide, were placed in two of the rows I had commenced hoeing, and which I wished to finish. I then stepped on one of the pieces of board, and hoed on as far as I could conveniently reach; then stepped on the other board in the adjoining row, and hoed an equal distance in that row. Then, with my hoe placed against a nail fastened near one end of the board, I moved the board I had just left, about two feet in advance; then stepped on it, and moved the other board in like manner. Then I hoed two feet ahead, moved my boards again, and so proceeded on to the ends of the rows. This process, although not quite as expeditious as without boards, not only left the ground in a very mellow state, but many of the fine lumps were broken which, by the common method of hoeing, would not have been. The land presented, after this process, the appearance of having had a roller passed over it, and I think it was better fitted to withstand a drought than it would have been if left in a rough state.

The onions were hoed three times, and at each time when the ground was in a sufficiently dry state to pulverize. The carrots were hoed in much the same manner as the onions, and, in addition, the ground was loosened up between the rows with a dung-fork just before the tops became so large as to prevent such an operation. The earth was not heaved up with the fork, as is commonly done in preparing beds for sowing, but it was barely loosened by running down the fork and giving it a pry. Some of your readers will perhaps think I am particular in describing my mode of procedure; and to such, if any there are, I would say, it was by attending to the small matters as well as the large, that, under Providence, I was enabled to realize so large a result.

The implement I have referred to for sowing the seeds I will now endeavor to describe. The bottom of an old-fashioned coffeepot was knocked out.* The pyramidal-shaped top was soldered on fast. A hole near one-third of an inch in diameter was made in the extreme end of the top for the seeds to run through. The whole was then inverted, and a handle near two feet long was nailed to one side to hold it by when in use. The seeds about to be sowed were thoroughly mixed with sand that was dry, and had been sifted to free it from lumps, small sticks, &c. On account of its simplicity and cheapness, on account of the even and *sure* manner in which

---

* By-the-by, I do not use coffee, as I deem it (unless in sickness) an unnecessary, and, to many, a hurtful drink.

it distributes the seeds, and on account of its being well adapted for sowing short rows as well as long ones, it is well calculated for extensive use.

I will also describe a simple, cheap, and useful instrument that I used to dig my carrots and parsnips. It was made out of a piece of large sized wagon tire about fifteen inches in length. One end was sharpened, and the other slit down near three and half inches. The part on one side the slit was left straight, to be inserted in the handle. The part on the other side was turned down horizontally, to place the foot upon when the instrument was in use. With one of these implements a man will dig, in a given time, one quarter more of parsnips or carrots than he could with a common spade.

S. S. G.

SANDLAKE, *December*, 1845.

LARGE CROP OF VEGETABLES.

James Robertson, of Windham Centre, New York, informs us that he gathered last year, from one acre and eight rods of land, the following produce:

Ruta-baga	819	bushels.
Sugar beets	134	
Carrots	132	
Total	1,085	

The ruta-baga grew on 122 rods of ground, and the sugar beets and carrots 23 rods each. The turnip ground, which was sod, was ploughed the previous fall, was harrowed well in the spring, and cross-ploughed in June, and fifteen loads of manure from the sheep house spread, and the ground again harrowed well. With a small plough it was then thrown into ridges about seventeen inches apart, and the seed sown about the 10th of June, in drills, and the crop was hoed twice. The beets and carrots grew on ground which the year before was occupied with ruta-baga. It was ploughed deep, and a light coat of sheep manure spread and harrowed in. The crop was sown in drills fourteen inches apart, about the first of May, and was hoed twice.—*Cultivator*.

APPENDIX No. 15.

CRANBERRIES.

From the Yarmouth Register.

PLANTING THE CRANBERRY.

In its wild or natural state, the cranberry is found in wet situations—in boggy grounds, in damp sandy lands, and on the low margins of ponds and streams. It will live and grow in comparatively dry soils; but it will not bear fruit without its roots are immersed in water at all seasons of the year.

Soil and situation.—The first object of the cultivator should be to select the ground for his *cranberry yard.* Every wet situation is not suitable. The soil must either be sand, mud, peat, or a mixture of these. There must be an abundant supply of water at all seasons of the year. If the ground is so situated that it can be flooded during the winter and spring, it is better; but it is not indispensable to success. The ground must be saturated with water, either from springs, running streams, or the drainings from higher land. On the low, sandy margins of ponds the water is not much affected by the season; a sufficient supply of moisture will ascend, because the little spaces between the grains of sand act as so many capillary tubes for the ascent of the water; but when the margin is compact earth or unmixed peat, the dampness will not, on that principle, rise to the surface. In a selection of a situation for his cranberry yard, the cultivator must observe—first, whether the soil is of a loose, porous character, easily permeable to water; and, second, whether there will be an abundant supply of water in the driest seasons. If either of these two requisites is wanting, it will be useless for him to attempt the cultivation of the cranberry.

Planting and culture.—In boggy grounds it is advisable to retain the top sod, and cover the surface with beach-sand, if it can be easily procured; if not, with any sand that does not contain loam or surface soil. Until recently, the common method of setting out the vines was, after the bog was covered with sand, it was marked off in parallel rows, like a field of corn, and sods of vines set from three to four feet apart each way. The usual method now is, to set in drills about two feet apart. The vines are separated, and only two or three upright stalks are set together, and are placed from six to twelve inches apart, lengthwise of the drill. On wet and barren sandy land the expense of setting out the vines is much less than on bogs.

Cuttings from any part of the stem will strike root, and may be used where it is difficult or expensive to procure a sufficient quantity with roots. Where vines cannot be procured, cranberries may be sown. It is not certain but that sowing will ultimately prove to be the cheapest and most expeditious method. We know of but one instance where cranberries were sown. That experiment was successful, and the ground is now thickly set with vines.

The best time for setting vines we are unable to state. The common practice has been to set them at any time, when the weather would admit,

from November to March. The spring we should think was preferable for sowing.

During the first season after they are set, vines frequently put forth numerous runners, four or five feet long. The next year the runners put forth upright bearing stems, which produce cranberries on the third year. The vines do not usually become so thick set as to cover the ground before the fifth year.

Manure is worse than useless, and any vegetable or animal matter that will cause fermentation is injurious. As a general rule, the *more barren* the surface-soil, the *better is it adapted* to the growth of the cranberry. The growth of the grasses in such situations will be feeble, while the cranberry, obtaining its sustenance mainly from water and the atmosphere, grows luxuriantly, and will ultimately *kill out the grasses* and obtain complete possession of the soil.

During the first three years, it is better to pull out the grasses than to wait for the cranberry vines to overcome them. Bushes must be carefully removed as fast as they spring up, because, if suffered to grow, they would do great injury. No other attention is necessary, excepting that good fences must be maintained around the vines to prevent the depredations of herbaceous animals.

Profits.—One bushel of cranberries to the square rod may be considered a good crop from vines that have been set five years, though we could cite particular instances in which three and four bushels have been gathered. Raising cranberries is like every other business in life: if a man judges rightly, is prudent and industrious, he will commonly succeed; but if he depends more on good luck than on good management, in nine cases out of ten he will fail. The cranberry fever is now running high among us, and almost every man you meet exhibits some symptoms of the disease. That fortunes are suddenly to be made by all who embark in this business, we do not believe; but that large profits can be obtained from vines set in good situations, such as are above described, there is no doubt. The experiments of Captain Henry Hall, Hiram Hall, and Peter Hall, of Dennis, of Captain Edward B. Hallett and Edward Thatcher, of this town, and many others that could be named, prove that the raising of cranberries, in good situations, is a profitable business.

We know that some of the opinions which we have given in this article will militate against the theories of a few of our friends; but we cannot help it. We have carefully examined almost every cranberry bog and yard in the county, and have carefully compared the information thus obtained, and we know that our opinions are corroborated and supported by all who have had the largest experience in the business. We do not wish to discourage any from planting vines: far from it. We say, go ahead. All we wish is, to discourage men from running blindfold into a business respecting which all the necessary information can be so easily and readily obtained.

NEW YORK FARMERS' CLUB.

We extract the following from a conversation at the meeting of the Club, as reported in the New York Farmer and Mechanic:

Gen. Chandler.—I present to the Club cranberry plants, (some with their

great crop of fruit on,) at the request of Mr. Sullivan Bates, of Bellingham, Massachusetts. A few years ago he first exhibited this fruit, produced by his new method—transplanting from low grounds to high. His success has been complete: he has gathered from one acre about 400 bushels of cranberries in a season! He plants them, in drills, 20 inches apart; in hills, 7 inches. The soil must be such an one as does not bake.

Chairman.—I took from swamps on Gen. Johnson's place some cranberry plants, and planted them on ground 80 or 100 feet above the swamp; they thrived, and their fruit was so close together that one could hardly put a finger in without touching the cranberries. It is a highly profitable crop. I am of opinion that five hundred dollars might be obtained for a full crop of one acre.

Gen. Chandler.—Mr. Bates will furnish any number of plants to those who desire it.

Mr. Worth.—The cranberry of Russia is larger than that of England; but both of them are scarcely half the size of these cranberries, and of much inferior flavor. Those exhibited here would suit the English and continental markets, and would be sold to any extent.

Chairman.—I planted mine in loamy soil; prepared the earth well about the plants; watered them well; and did not lose ten out of the one hundred and fifty plants.

Gen. Chandler.—And those which I set out last spring lived and flourished.

Mr. Wakeman.—My family have tried Mr. Bates's cranberries, and found them excellent. They are larger than other cranberries.

Dr. Underhill.—The cranberry probably improves in *all* respects by the transfer from marsh to upland. Wild grapes love alluvial, wet positions; but their flavor is not to be compared with those growing in dry soils. The wild grape has a thick skin, hard pulp, large seeds. By culture in dry situations, the skin and seeds become one-half less thick and large, and the pulp almost disappears.

APPENDIX No. 16.

GRAPES, PEACHES, &c.

For the North Carolina Farmer.

BRINKLEYVILLE, HALIFAX CO., N. C.

DEAR SIR: In your first number of the North Carolina Farmer, I see you publish an extract from the American Agriculturist, on the culture of the vine and wine making, &c. While according due merit to that piece, as to many particulars, and while allowing that, as to kind of grapes and mode of making wine, they may do in northern latitudes of our country, I am bold to aver that the system, as such, will not do south, for I have experimented on it without success; and I have known a number of others likewise to have failed, so far as that system is concerned. For instance, the Isabella grapes, after a few years culture in our soil and climate, will rot on the vine, in a majority of seasons, in spite of remedies; and the quantity of sugar will not do to save the wine in our hot climate. Neither will fermentation, without straining, generally succeed.

But, without further remarks on particulars at present, I send you the "New York Farmer and Mechanic," in which my uniformly successful process of wine making, with sugar, is detailed.

I would add, that if brandy is added, (as I make a part of my wine therewith,) a fourth of good spirits is not too much to insure the safety of the wine, as well as to give it a good body, seeing American grapes are not as saccharine as European. Indeed, if vineyard business is pressed in our State, the best use of spirits, (apart from medicine direct,) I consider, is to mix it with grape-juice for wines, and thus render its qualities not of the same fiery, intoxicating nature.

As to kind of vines, I will communicate again for your valuable periodical, if you think best to insert this and the extract named.

In the mean time, yours, with all due respect,

SIDNEY WELLER.

From the Farmer and Mechanic.

VINEYARDS AND TEMPERATE USE OF WINES.

MESSRS. EDITORS: Through a desire of being humbly instrumental in promoting the temperance cause of our country, by discouraging the use of ardent spirits, I was induced to undertake the vineyard business as an incidental agricultural employment, on my plantation, in this part of North Carolina. So far as tried, the experiment has answered my expectation; for, the substitution of unequivocally pure and healthful American wines, I have found, answers all the medicinal purposes of an alcoholic stimulant, where such is required to be used, without the inflaming and insidious use of ardent spirits. My wines in this region are now preferred by many, as a family medicine and for communion occasions, to those of foreign countries, of doubtful purity; and we find that the wines mentioned as blessings in the Holy Scriptures were those of *Palestine*, not *exotic*. This

affords a good hint for Americans no longer to expend millions for foreign wines, when our own soil and management are capable of as good, if not better. Indeed, from the general principle that Providence, in the way of food and medicine, generally supplies, of spontaneous growth, every region of the world most suitable for the inhabitants of such region, we might argue that the very luxuriant growth of the vine in most parts of our country indicated it to be wrong for us to depend on the east for grapes, vines, or wine. Be that as it may, I may be permitted to state—and that from the best information, as I think, on the subject, as well as from twenty years' of experience—that this part of our country is as well calculated, in soil and climate, for vineyards and wine making, as any part of Europe. According to the best accredited information, I have made, I have reason to believe, more wine from an acre, or at rates of more, than has been made in France, or other wine-making countries of Europe. And I am not alone in considering the wine from my vineyards as good as the foreign; for, not only in this region I have this testimony from reliable sources, but from different parts of the country whither I have sent my wines, both north and south. For instance, I lately had a letter from a gentleman in Natchez, Mississippi, saying that my wine was highly approved by gentlemen there. I have exceeded my expectation not only in quality but quantity of wines from my vineyard, and in seeing others embarking in the vineyard cause, and therefore look forward to the time when our country generally may have her supplies of wines at home used, generally, in lieu of ardent spirits. By enlarging year after year, I have now about six acres of vineyard; some vines small yet, but a portion on canopies, or one continued spread of branches and foliage above, and all completely clear beneath, six or eight feet high, except the posts to support the scaffolding. From former yield and ratio of increase, I calculate on upwards of forty barrels of wine the coming vintage. The severe frost on the 8th of April last did not injure my prospects of a grape crop; though most all peaches, pears, and apples, and other fruit, were destroyed.

As North Carolina excelled, according to the last governmental census, in the agricultural product of wine, and as I have reason to believe mine is the most productive vineyard in the State, I hope it will not be deemed presumptuous for me to give to the public, through your columns, a uniformly successful mode with me in making a good, well-keeping, sugared wine. I say sugared, because (a fact owing perhaps to the very luxuriant growth and abundant productiveness of vines in our country) the juice is not so saccharine as in Europe, and the weather is also warmer, so that some ingredient has to be added generally to insure the keeping of the wine.

A safe quantity of sugar is two pounds to the gallon, but more or less according to the kind of grapes, and their ripeness when gathered. The following is an outline of the process:

1. The grapes, gathered and cleaned of all but sound and ripe ones, are mashed, with us, by a machine of two rollers, turned by handles.
2. The mass is then folded in a sheet, within a crib, under a press, and the juice extracted, in the same manner as cider.
3. Over a tub, and on a frame, are placed several folds of woollen blanket, (to be washed or renewed when impervious by sediment,) through which the juice is measurably purified by straining, as it were, into the vessel.
4. Add immediately two pounds or more of sugar per gallon. If want-

ing a very fine costly wine, take the best double-refined loaf sugar, beat up. But the common brown will do for a very good wine, of less delicate flavor.

5. Into a clean wine cask, new or second-hand, fumigated with a sulphur match, put your juice thus prepared, and no further process is needed after putting away your cask, bunged up, into a cool place or a cellar. The wine may be left on the lees, to be drawn off for use when wanted, by a spigot, so high as to be fairly above the lees or settlings; or, without any artificial fining, it may be racked off the following fall or winter, when a gallon or more of settlings from moderate (because strained as above stated, and thus kept from running into the acetous state by too violent) fermentation will be found. My Scuppernong, so much commended abroad, (as by members of the American Institute, according to the statement of Mr. Boswell,) is made precisely as above stated, with the double-refined sugar.

But, to make a dark red wine of colored grapes, after mashing I put the mass into an open-headed cask, covered with a blanket, and let it ferment till the skins, &c., float on the surface, and draw off *that* underneath by a spigot near the bottom of the cask; strain it as above stated, and then put in the sugar, and turn it into the cask, and the after treatment is as that stated before of the wine not fermented with the skins, &c.

If sugar enough be added of good quality, and strained as just stated, there is no danger of the wine running into the acetous fermentation.

A few words as to the temperate use of wine, and I close this communication, now longer than intended when I began it. The Scripture, properly understood, I consider the true criterion of the *proper use* or the *abuse* of any blessing of Heaven; that is, of *temperance* or *intemperance*. The express and implied direction to Timothy, as to wine, may be viewed as a very fair general exposition of the Bible doctrine on the subject.

Timothy was to use a *little* wine for his *stomach's sake* and *infirmities*. Now, a fair implication is, that if his stomach or infirmities had not required it, it would not have been his duty to have had recourse to wine at all. And a fair inference therefrom, and that which accords with the strongest light of experience, is, that to those in perfect health the stimulant of wine is needless; and if anything *needless* be resorted to, it is in danger of becoming *pernicious* at length.

Again, if a well man habitually drinks wine, or any other stimulant, he anticipates every good effect it might have when he becomes sickly or infirm. So, it is a *most wretched policy*, to say the least, for the young and healthy to practise taking wine, or any other stimulant; according to the striking moral in the account that a certain *well* man took *medicine* to become *better*, and, while dying in consequence, dictated his epitaph, viz: "I was *well:* I took *medicine*, and *here* I am."

In haste, yours,

SIDNEY WELLER.

BRINKLEYVILLE, HALIFAX CO., N. C., *June* 22, 1845.

From the Albany Cultivator.

CULTURE OF THE GRAPE.

MR. EDITOR: My plan of a vineyard, after the vines are scaffolded, is, in brief, to have no impediment to a free passage of men, cart, or team

beneath the scaffolding, nor anything seen for several feet high but main stem of vines, and posts; and swine always kept in the vineyard to help to keep the ground clear of grass and weeds. When necessary, I use the harrow, skimmer, plough, or cultivator. And especially, before an expected frost or severe weather to cause the leaves to fall, I scarify the ground; and again, after they fall, I run over the surface with some instrument to incorporate the leaves with the soil, to prevent their blowing away, and to answer in lieu of manuring. Trimming in the summer and early in the fall is good for all vines, (so far as trimming is necessary,) but especially so for the Scuppernong. No danger of bleeding at these times; and these last named vines especially should have plenty of room to expand, say thirty feet apart; not too great a distance when considered that ere long, with good attention, they will form a thick, complete canopy, at that or even greater distance. Other vines, ten feet each way is the common distance. Ten feet also the common distance for all my posts to support the scaffolding.

In haste, yours, &c.,

SIDNEY WELLER.

Brinkleyville, N. C., *June* 6, 1845.

For the American Farmer.

AN OUTLINE OF AN AMERICAN VINEYARD, FROM THE START.

Mr. Editor: The following outline is the result of years of successful experiments:

1. Select the best tested American grapes, particularly such as are found to mature well, whether the vines are young or old; if you wish such as will bear forthwith, take those well rooted, of several years standing in the nursery.

2. Plant in the manner of fruit trees, ten feet each way, except the Scuppernong: twenty feet for them.

Trim in the summer or early in fall, tying up one or two main stems, unchecked in length, to stakes, for a year or so; after which, insert a post, with two cleats nailed each side of the upper square end to hold rails or scantling for making the frame for the outspreading canopy of vines above. After the vines have started over said frame, no more trimming is necessary, except it may be to cut off any straggling branches under the canopy, that all may be kept clear beneath for say six or seven feet high.

3. As to soil, any will do, with proper management. I have the finest of good bearing vines in almost all kinds; from the light sandy to the stiff clayey. And as to strength of soil, there is more danger of having land too rich than too poor, as to the bearing properties of vines. As a general principle, ground that will bring good corn is plenty rich for vines, provided you dig or plough, or both, some depth and width, when the vines set, and put manure or surface soil at the bottom of the opening, and then cover with common earth before planting, that no manure or too rich soil may come in contact with the roots, to endanger their safety in case of a drought the first season after planting.

4. The best mode of keeping up due fertility of soil is this, viz: In connexion with never suffering your vineyard at any time of year to be-

come grassy or weedy, to be particularly careful to scarify the ground; and, after fall frosts, let no leaves or litter from your vines blow off or become incorporated with the soil beneath the canopies. Nature's mode of keeping up and increasing the fertility of woodlands taught me this mode, and the very best, too, of manuring vineyards, or what is more than equivalent thereto.

5. The foregoing is the whole secret of having a first-rate vineyard, the *ripe* fruit of which is the most healthful as well as pleasant, and can be enjoyed for several months in the year; the wines from which are in no danger of adulteration; and, as to a family medicine, according to the voice of experience and of most eminent physicians, the very best single healing one in the Materia Medica; and also an anticipator of disease in sickly places and seasons, when taken temperately—say after dinner.

A few additional little matters, and I close this off-hand, hastily written article.

1. I tie my vines with elm bark, which, being got in spring, is at any season ready when soaked, and outlasts any strings I have ever tried.

2. In a wet season I insert posts, with what we call *jobbers;* that is, a piece of wood say three feet long, sharpened at one end, and a strong peg inserted through the other end for raising it by a stake or crow-bar, when driven into the ground by a maul or beetle. Into the hole made thereby insert your post, say two or more feet deep.

Posts at any time can be renewed, when giving way, by propping up the part of the canopy above. Posts of any lasting wood had better be charred at the little end, so as to stand inversely from the way they did when growing as a tree. According to statements I have read in agricultural periodicals, they will last much longer when thus inverted, or standing, as it were, upside down.

Pardon the hasty and desultory style of this communication, and believe me ever yours, and a hearty well-wisher of all deserved success in your avocation in the best of all arts and sciences, as that of agriculture is the foundation of all the rest.

Yours, &c.,

SIDNEY WELLER.

BRINKLEYVILLE, HALIFAX Co., N, C., *Sept.* 16. 1845.

VINTAGE OF OHIO.

I promised you an account of our vintage. It is over; and after all complaints of the rot, and dropping of fruit, and the lamentations of the hard-working German women, who do most of the work in the vineyard in the summer season, my tenants have cause for gratitude, not complaint. The promise of the crop early in the season was without a parallel. Their expectation was 500 barrels of wine. They have made upwards of 300. The mash was very rich, and the wine promises to be of fine quality. More is said of the quantity of wine raised in this country than is true. The balance of the State, I venture to assert, has not produced an equal quantity. But the cultivation of the vine is fast extending on the Ohio; and one or two years more, and I trust the same remark would not be true of this country.

I am also extending my vineyards. As an inducement to poor Germans,

I will give the result in a single vineyard—that of Tuferbers. It is situated four miles from the city, on Boldface creek. It is a rich, steep, stony hill. It resembles the hill of the Irishman—"So steep, that before you get up on the one side you are half way down on the other." It was a hard bargain to the tenant. To trench, bench, and wall the south side hill, was worth $300 per acre.

* * * * * * * * * *

After three years' trial I parted with him. I then took the present German tenant. He was very poor, but strong and healthy—his wife a match for the wife of my other German tenant, who, when she died, told me "he might just as well have lost his horse." He had also full-grown boys and girls. I made a hard bargain with him. Bound him to trench and bench six acres of the worst ground in three years, and plant it in grapes, and put out fruit trees. I was to have half of the proceeds of all the wine and fruit. Space was allotted to him to raise cabbage and potatoes for his family and pasture. I was careful not to make an attempt to climb the hill for the three years, or go near it, fearful of disappointment. Judge my surprise, at the end of three years, to find six acres handsomely trenched and benched, with their walls and vines in fruit. Peaches and apples were this season a total failure, and he had his grapes only to rely on. This is the only vineyard at which a few Isabella grapes remain. To encourage him and the other vine-dressers, I let them have my share of the wine at a reduced price. For the Catawba, he was to pay 75 cents per gallon; for the Cape Vevay, or Schuylkill Muscadell, 62½ cents per gallon; for the Isabella, 50 cents per gallon. The whole of his enclosure does not exceed thirty-five acres—nine acres of it in grapes. He has sold his wine of this vintage, for cash, for $1,779 41. At the price my share was sold to him, it came to $713 75, and left him, from the vintage, the net sum of $1,065 66. I trust other poor Germans may be excited by his example. The thirty-five acres cost me $630. There were some vineyards in the neighborhood more productive than any one of mine, as they suffered less from late frost and the rot.

N. LONGWORTH.

CINCINNATI, *October* 7, 1845.

From the Indiana Farmer and Gardener.

LONGWORTH'S OHIO GRAPE, &c.

In our last we gave an account of a Herbemont grape at Madison, Indiana, supposed to be identical with Longworth's Ohio. We have received from Mr. Longworth a statement which puts all aback again. We have both grapes in our garden, and hope to be able to compare them the ensuing season.

CINCINNATI, *April* 24, 1845.

To the Editor of the Indiana Farmer and Gardener:

DEAR SIR: Your correspondent, Mr. Morrison, is in error in supposing the Ohio grape and Mr. Fitzhugh's Herbemont the same. The latter grape I obtained from Mr. Herbemont many years since, with samples of

his wine, which were not good. Mr. Fitzhugh, of Madison, sent me a sample of wine made by him from this grape, of fine quality and greatly superior to the samples of Mr. Herbemont, and satisfied me that our climate was more suitable to the cultivation of the grape than South Carolina. The sample of the Herbemont sent by Mr. Fitzhugh was examined by the society and pronounced the Herbemont Madeira. It is a fine table grape, entirely free from the hard pulp common to most American grapes, and superior for wine to the Ohio grape, but the bunches are much smaller. The Ohio grape has borne well with me, in my garden; but at my vineyards, in the High Hills, it bears badly. I have never seen it injured by frost. An account was published a few years since of upwards of three thousand gallons of wine to the acre, made by Herbemont, from his grape. Such statements are ridiculous. He had four or five vines that covered his house and porches. The stalks covered but a few feet of ground, and, so measuring, he had more than 3,000 gallons to the acre. In his vineyard he never raised 200 gallons on an acre. The Catawba grape is a good table grape, though not entirely free from a hard pulp; but as a wine grape, in our climate, I consider it superior to all others—capable of making a wine to rival the best Hock and Champagne wines—and that Major Adlum, in introducing it, has left a mine of wealth to the people of the Ohio.

I make this remark, as a gentleman from the east observed to me a few days since that it was understood I gave the preference to the Isabella. The latter grape succeeds better [at the east] than with us. I deem it a poor table grape, and worthless for wine, and have extirpated it from all my vineyards. With two pounds of sugar to the gallon, it makes a pleasant sweet wine.

Yours, with regard,

N. LONGWORTH.

SELECT AMERICAN GRAPES IN THE BRINKLEYVILLE (NORTH CAROLINA) VINEYARDS.

Our successful experiment of grape culture and wine making is mainly attributable to the system being *American* throughout; and, as to the kinds of grapes, not only, after trial, rejecting foreign, but also such natives as are not profitable in most respects. On canopies supported by posts ten feet each way apart, and all clear beneath, for passage of wind, persons, or teams, might be seen, a month since, a complete spread or sheet of grapes, so thick in many places as to yield at rates of a thousand and more gallons of wine per acre. And now, after having made our barrel of wine a day for some weeks past, and entertaining visitors, sometimes more than twenty a day, the vineyards are very full still, and a stranger might conclude that few grapes had been abstracted, and those only from some vines. But, designing a mere list of most select vines, with a passing remark or two, we proceed at once to enumerate, first, such grapes as are good and profitable in every respect, and from most of which we make not only gallons but barrels of wine annually, of late years.

1. The white Scuppernong, the noble native of our own State; but north of latitude 37½ degrees, of no peculiar excellence.

2. Weller's Halifax, a native of this county, but calculated, so far as we have learned, for any part of our country. Out of a large number of vines from the seed of this grape, one we call the Halifax seedling promises, according to best judges, to be inferior to none in every respect. Its culture is yet limited. Fruit like the Catawba, but sweeter.

3. Vine arbor; so called from its very large leaf, as well as extended growth, and consequent peculiar fitness for arbors.

4. Somerville.

5. North Carolina. This is late in ripening, and its peculiar excellence is for wine, not table use.

6. York Madeira.

7. Fragrant. This delightfully perfumes the air around, when ripe. The above kinds have all large berries, and average the Isabella and Catawba in size, and consequently are not subject to depredations from birds. We have several other fine sorts of like sized grapes. But we proceed to those of intermediate size (or that, say, of buckshot) in our first class, viz:

8. Norton's Virginia seedling, called after the late Dr. Norton, of Richmond, Va. This we find one of the finest in all respects, as for table use, wine making, productiveness, (capable of 2,000 gallons per acre,) and free from rot.

9. Cunningham. This is also a grape from Virginia, most excellent for eating, and with one difficulty only as to wine qualities, viz: on every raceme some small green grapes are interspersed among the ripe ones. But, to obviate this, we omit picking out the green berries, and make the wine in the way the late Mr. Herbemont made his Madeira, or a white wine, from his colored grape; that is, by putting the grapes unmashed under the press, and, after pressing, the ripe grapes only are found mashed by pressing.

10. Woodson, also from Virginia; much later ripening than the Cunningham, and not so good for the table.

11. Lenoir, a grape of a grade smaller berry—among the first of peculiar excellence in ripening here.

In the fine vineyard of Mr. John Carter, near Richmond, Virginia, he showed me, some years since, the Clarence of France, imported by him as *identical* with the Lenoir. If Mr. Carter is not mistaken, this is a foreign grape, only not subject to rotting in our country. The juice is very strong, and, as the late Mr. Herbemont observes, capable of making a good keeping wine, without the addition of either spirits or sugar.

But, omitting further enumeration of excellent grapes of intermediate size, we proceed to the second general class, viz: of some kinds excellent in many respects, but exceptionable on account of propensity to rot, (at least at the south,) smallness of berry, &c., and therefore no dependence on them for a wine crop; though a few of each are retained in the vineyards as a variety of fruit, and in contrast, and for visitors. Among a considerable number of kinds in class second, the following are here noticed:

1. The Catawba, the favorite grape of Mr. Adlum, Georgetown, District of Columbia, and now, I see from agricultural periodicals, mostly cultivated in the northern and middle States. But its proneness to rot on the vines renders it a very uncertain fruit in the south, and the older the vines the worse; so that some, as I learn, in this State and Virginia, have given up vineyard culture in despair of profit, whose principal vines were the Catawba; and,

2. The Isabella; and no effectual remedy have we found for this tan-

talizing casualty, but that of cutting down, in the fall season, most of the vines of these sorts, and grafting on their stocks some of the first general class, as good at least in every respect, and far better as to certainty of a well matured crop. Three years since we procured a kind of Catawba said not to rot. The young vines of what we call Eaton's Catawba, so far, have matured their fruit.

3. Colesvine.
4. Alexander.
5. Constantia, or Vevay. This last is that chiefly cultivated by the Swiss settlers in Indiana. But, however succeeding with them, when the vines are young, at least, it proves here one of the rotting kinds; although it, as well as all just named, produces fine large fruit when happening to mature.

This second class now continued with grapes of intermediate size; as,

6. Herbemont's Madeira. This, as seen in the columns of the "American Farmer," was called the Warren, or Warrenden, ere it received the above name from the late excellent Mr. N. Herbemont, of Columbia, South Carolina, who gave it notoriety. It appears to be of foreign extraction, from the shortness of the vine joints, and especially its proneness to rot. Mr. Herbemont himself calls it a tantalizing grape; because, as he states, just when giving promise of an abundant yield, (once he made at rates of more than 2,000 gallons per acre from it,) its frequent habit is to begin rotting without any assignable cause of too wet or too dry, or the like.

7. Longworth's Ohio. The distinguished agriculturist, Mr. N. Longworth, near Cincinnati, sent me, a few years since, some cuttings of this, by mail, in a newspaper; and, by grafting, I have cultivated it to some extent. But here it is of no peculiar excellence, and, I find, prone to rot, though Mr. L. informed me it had proved a most excellent variety in his locality.

We have procured from nearer and more distant parts of our country a considerable number of other kinds of intermediate sized berry, and exceptionable in some respects; among which I name—

8. Baltimore seedling;
9. Bland's Madeira or red English;
10. White English;
11. Enfield;
12. Hunterville, &c.;

and also several varieties of small berry and small yield, though otherwise fine. Three only of these we add to our list of the 2d class, viz: 13, Wilcox; 14, Guinard's native; 15, the Elsingburg.

We have under trial a large number of seedlings; and of those procured from everywhere we could hear of a good native, and may give the result in due time.

SIDNEY WELLER.

Brinkleyville, Halifax Co., N. C., *Sept.* 15, 1845.

CULTIVATION OF THE GRAPE.

James Locke, florist, of Sing Sing, New York, writes to the New York Farmer and Mechanic, under date of August 4, 1845, as follows:

When you were last at my place, you requested me to send you a written statement of my mode of treating the grape vine. In the first place,

I dig a hole two and a half to three feet deep, according to the length of the vine—never less than two—about three feet square. My reason for doing so is, to get the roots beyond the influences of the sun, as they are naturally inclined to approach the surface, causing the vine to throw out an unusual quantity of foliage and fruit; and when the dry season commences, they feel the drought immediately. After the vine has been established for three years, I dig down and cut off every root from the main body. In doing so, I dig a trench each side of the vine a foot deep, from two to three feet wide, and fill it up with all sorts of rubbish, such as pea-brush, bones, shoes, &c. I chop up all my vine trimming in pieces of about eight inches in length, and throw them in the trench. I then throw the ground taken from the ditch over the whole, then cover the surface, as far as circumstances will permit, with long litter, pea-brush, &c., in order to exclude the sun as much as possible. By excluding the sun the ground becomes moist, and is pierced with thousands of angle worm holes. Whenever we have a shower, the rain filters through, and is carried down those holes to the roots. I do not think it necessary for the sun to touch the earth at all; and this I think I have fully proved. I have one grape vine that I planted in the rear of my kitchen, which it afterwards became necessary to occupy for a wood-house. Not liking to cut it away, I bent it down and laid the floor over it, so that it has been with the roots entirely under the building. Every year this vine produced as much fruit as it is capable of sustaining. It has a northerly exposure, and the grapes are usually the first ripe on the place. I do not think the berry quite as large as those that stand in a more open exposure; but the flavor is equally fine. I have one vine that has a westerly exposure, planted shallow, and the surface not covered: this dry weather, the fruit has entirely perished. The next vine to it was planted in the same exposure and same depth, but was afterwards filled in so as to bring the root about three feet under the surface, which was not covered with rubbish; the fruit has not wilted, but is not near the size of those vines which had a covered surface. I have one perpendicular arbor running due north and south, and from the top of the arbor I have conducted several vines east and west. The fruit on the vines running west ripens ten days sooner than on those running east. I have changed the vines, and the result was the same. I occupy no more ground with that arbor than the mere width of the post, which is about seven inches; and I cultivate on each side of it, close up to the post. I do not think it necessary, in order to cultivate grapes to any extent, to occupy any more space than the width of the post. I think the vine is all the better for having any sort of a green crop on the surface near it, so as to exclude the sun.

If I were going to set out a vineyard, I should set a row of posts six feet apart, then another row of posts parallel to them, thirty feet distant from the first row. I would then plant a vine at each post, and conduct a No. 12 wire from the top of one post to the other. I then could use the intermediate ground for any short crop of garden vegetables I wished. They would all do well; and, by training a single vine up the post, across the wire, I would get full as many grapes, if not more than when the whole arbor was occupied; and the wind has no effect upon it, the wire being so flexible that they do not suffer as much as those that are trained on an arbor. The posts ought to be high enough to drive under with a horse.

My time of trimming is late in the spring; at least I never commence trimming until the vines will bleed freely, which a great many people con-

sider a great detriment; but when I cut out old wood, I always cut it three or four feet longer than I intend it shall be, so that when the first cut becomes gummed over, I cut away some more, to give the sap a free passage. I will venture to say my vines are the largest in the State of New York, for their age. The great difficulty with me is, that they are so loaded with fruit that I am obliged to pick off large quantities when green. In consequence of the superior flavor of my grapes, owing, I think, to the surface of the ground being covered and tilled, I have no trouble in selling them in advance, as I have now done for the last two years. Messrs. Hope, corner of Chamber street and West Broadway, have engaged them.

In trimming, I suffer no old weed to remain that I can possibly remove, and trim the ones I wish for bearers entirely smooth. I also make a second trimming in the course of the season, by removing the middle growth.

For the Farmer and Mechanic.

GRAPES.

Mr. Editor: I have just read in your valuable paper an article on the culture of the grape, by James Locke, of Sing Sing. Mr. Locke appears to attach much importance to deep planting, or compelling the roots of the vine two feet below the surface. Dr. Underhill, too, favors the same opinion. Is not this altogether at variance with agricultural chemistry? Such is my impression from reading Liebig, Johnston, Dana, and others; but, independent of these, I know from experience that it is altogether wrong. It is an old-fashioned practice in England to make vine borders of prepared compost to the depth of six feet. I have had occasion to overhaul these several times, and invariably found the bottom of the border totally unfit for any plant to live in. Ten years past I had the first opportunity of seeing the grape vine in its natural state; and, being passionately fond of growing the grape vine, I examined them closely, in the woods, on the banks of the Hudson. I have dug up dozens of them, and invariably found their roots within six inches of the surface. From the past season's experience, I am more than ever convinced that to plant the grape vine deep, or, which is the same thing, to fill up so as to bury the roots two feet below the surface, is detrimental. In the situation I now am, I have the charge of three vineyards; in the first of which the vines (six years ago) were planted too deep—consequently did not thrive well; to remedy this, fresh compost was added the next season, but without benefit; another gardener came—two or three in fact—and ("a curse, by the way, to most vineyards, this repeated changing") each of them took the same course; so that the roots (that is, the original roots) were buried all of three feet below the surface. When I came this past spring, I forked up part of the border very carefully for fear of injuring the roots, but was surprised not to find any within reach. I then took a spade and dug down two feet, six feet from where the vines were planted, and there found some brown looking roots, which I traced to their extremities, and found that the whole of last season's formation had decayed. I then gave up all hopes of perfecting a crop of grapes; but, luckily, there was a small space of about four feet in width from where the vines entered the house to the flue that had been filled up for salad, &c, and into this border the vines had rooted from the stem.

With these roots, well fed with guano, liquid manure, &c., and with the few roots made from the stems on the outside of the house, "near the surface," I have ripened a crop of grapes averaging twenty pounds to the rafter—being the first *crop* of grapes ever brought to maturity in this house since the vines were planted—and some of the fruit judged of sufficient merit to take the second premium of the State society.

I visited the vineyard of Dr. Underhill about four years since, in company with another gardener, and thorough grape-grower, too, and it was the impression of both that the grand secret of the doctor ripening his grapes so uniformly was a remarkably light sandy soil; the roots near the surface, and yet prevented from being scorched with the sun by a liberal application of swamp muck as a top dressing—apparently not intended as a manure, but to preserve a uniform temperature in the soil.

Cutting off the roots of the vine does not prevent their finding their way to the surface; it may do so for a short distance, but it should be borne in mind that the vine is a great rambler, both top and bottom; and, after cutting off all the roots two feet below the surface, it may still be a fact that the spongioles, on which the vine depends for nourishment, are found close to the surface, though it may be at a distance of fifty feet from the vine.

Mr. L.'s plan of training and pruning the vine I like very much; I believe it to be the only plan of growing the native grape so as to obtain fair bunches of well flavored fruit, but think the less he crops the intermediate space the better. For the first three years after planting, two or three rows of potatoes might be taken off; but after that, keep the surface covered with muck, and the cultivator freely at work.

Very respectfully yours,

G. K.

Newark, *September* 20, 1845.

From the Visitor.

* * * * * * * * *

But I sat down to tell you something about my grape vines, and now I will stop rambling and do so. Having a spot on the south side of my house which I thought would be favorable to the growth of grapes, in the fall of 1842 I erected an arbor by setting posts, leaving them eight feet out of the ground and fifteen feet from the house. On the tops of the posts one end of a sixteen-foot scantling was rested, the other end resting against the house, sixteen feet from the ground. These scantlings were crossed with two-inch strips, about two feet apart. The upright posts were also crossed in the same manner as the top of the arbor. Early in the following March I dug a trench at the foot of the posts, two feet wide and three feet deep. I then filled it half way up (eighteen inches) with oyster shells, and the remaining eighteen inches with loam taken from the commons near the city. In this loam I immediately set my roots, having vines attached to them of about two feet in length. Directions were then given that all the waste water from the kitchen—dish-water, soap-suds, &c.—should be daily thrown around them, which was done. One of the vines blossomed and bore the first summer; but an unlucky boy, strolling into the garden, broke off all but a few grapes, which ripened, and were found to be delicious. Their growth this first summer varied from five to ten feet in length, besides throwing out great numbers of lateral branches. I did not trim them

at all the succeeding winter. Early in March last, it being the second spring only that they had been in the ground, they began to put forth. I do not remember the time of their blossoming, but in July the neighbors began to pick, and pronounced them ripe. This, however, was not the case. The vines then, notwithstanding the severe drought which had prostrated almost every thing around us, presented as beautiful an appearance as I ever beheld. Thousands of branches and tendrils had put forth, the leaves were large and fresh, and the fruit hung under the trellis-work in delicious and tempting profusion. The branches were not so numerous as I have oftentimes seen them, but they were twice as large as any other that I saw during the summer. One vine, however, of the bigness of a man's finger, contained *one hundred and twenty bunches*, all perfect, and of extraordinary size and flavor. These were the Isabella; the Catawbas did not yield so abundantly, and the Sweet-water not at all, as yet. The latter had not the advantage of the trench and the oyster shells, but in other respects were treated the same. During the extreme dry weather I occasionally threw fresh water upon the vines from a watering pot, and from a large syringe where they were high.

In this my first attempt at raising grapes, I have been highly gratified; and, from the experiment, I am satisfied that the vines require a great deal of water, but in small quantities at a time, and that it should never stand long about the roots. The oyster shells serve as a drain to carry off water which might otherwise remain too long; and as it percolates among them, it carries down the fine mould, which the small, delicate roots soon find, and thus, below the effect of drought, find a never failing source of nourishment and support. In the autumn I throw around the roots a thin coat of coarse manure, old bones, and chips.

A gentleman in Rochester, New York, who has a fine grapery, informed me last summer that he put up grapes for use in the following manner: Place a layer of cotton in a barrel, and then select such grapes as are perfectly ripe and lay them upon it; cover them with another layer of cotton, and so continue till the barrel is full; then place the barrel in a dry place, out of the way of frost, and they come out through the winter in all the pulpy lusciousness of a bunch freshly plucked. * * * * * A portion of these grapes, thus preserved, remained upon the vines till into October, when they were as rich as any foreign grape that I ever tasted. I am confident that most of our grapes are eaten before they are ripe. I intended to have made the experiment of putting them down in cotton, but they proved too tempting to remain on the vines in sufficient quantities. A neighbor has made it, however, and I expect soon to learn with what success. I think the vines should be trimmed early in January. This climate is highly favorable to the culture of the grape, and nothing is wanting but a little pains to produce them in any quantity. I should be glad to know how attempts to cultivate them succeed in New England.

Truly yours,

SIMON BROWN.

As yet, little has been done in New Hampshire to advance horticulture. Even the profits and the gratification from the production of that excellent fruit, the apple, are as yet but beginning to be realized. The best methods of cultivation are yet little understood. Our soil and situation are most favorable for the apple. We believe the time is coming when the peach

may be common. Pears and plums will also adapt themselves to our climate. There are kinds of our own native grape which, by cultivation, may here be made equal to the Isabella, the Catawba, or the Sweet-water. Let Mr. Brown's mode of thorough cultivation be marked, "set in a note book, learned, and conned by rote," by men of curiosity and leisure, and we dare say these northern latitudes will secure to us abundance of grapes as good for use at least as the Smyrna grapes, for which those who get up genteel entertainments pay an expense of thirty seven and a half cents per pound—a price at least four times as great as any food to pamper the fastidious palate should cost.—*Editor of the Visitor.*

NATIVE GRAPES FOR WINE.

The following is extracted from a letter of a gentleman in Alabama, whose name and residence are not given. It is possible that some of the native grapes, much inferior to the Catawba in flavor, may prove to be the best for wine. The wine grapes of Europe are generally very inferior as table grapes. A gentleman in Mississippi City cultivates a small native grape which is said to make an admirable wine:

"I make, annually, for my own use and to scatter among friends, from seventy-five to one hundred gallons of wine. I prefer it for a summer drink, using no spirits. The red wine was made from our native, uncultivated grape, which abounds through this section of the country; some of the finest varieties of which I am cultivating, previously having determined their qualities as regards producing a good wine.

"There is an astonishing variety in the product of our native grape, all of which are cultivated with great ease, and exhibit, on cultivating, an improvement hardly credible.

"Among other properties possessed by our native grape, the quantity of vinous matter they possess is most remarkable. A bushel of bunches, as pulled from the vine, will give three gallons of the wine I sent you; and, after undergoing a second operation, about one gallon more, of a lighter but most agreeable wine. It would take a third pressure to produce the meagre drink with which they in part feed the peasantry in France, &c., who tend the vintage. I anticipate most agreeable results from the cultivation of our native fruits, based on the trials I have already made.

"The white wine I sent you is from an American grape, acclimated to this section of the country many years ago. It is a reddish-colored grape, resembling the Catawba, exquisite for the table, a great bearer, and hardy.

"As regards the cultivation of the grape, and wine making, I have effected one most desirable object, viz: doing away altogether with that great expense, of which so much has been written and said. The ground in which my vines stand and bear produces me annually two other crops—say a crop of Irish potatoes, and, after they are matured and taken from the ground, another crop the same year of a variety of the red sweet potato, a most valuable variety for stock, and most productive. My mode of supporting the vine is simple, efficient, and economical. The manure given to the Irish potato crop is ample for the vines, and applied in the best possible way. The superiority of the grapes I produce, as regards quantity and quality, has been often loudly remarked by our own citizens and foreigners.

"I have a splendid collection of the apple, all acclimated. The cider apple is, perhaps, the most beautiful tree of the kind you have seen; a most free grower, and prolific, bearing annually full crops. It is the best apple to hang on the tree, and the freest from rot, I have ever seen. It cannot be surpassed in the Union. It is a native of Alabama, produced from repeated planting of seed, and grafting and regrafting, for the last twenty-five years.

"A vineyard at maturity—say the fourth year—would be good for from five hundred to seven hundred and fifty gallons; the seventh, for one thousand gallons; the Scuppernong much more to the acre.

"My mode of planting and cultivating the grape—half the quantity per acre—and the annual crop mentioned, please me better. Ground with us is plenty, and potatoes are as essential to our comfort as wine. In fact, in every species of cultivation I am every day more convinced that mixed cropping is the true mode of employing soil and labor. In this way the expense and labor are singularly decreased in proportion to the product.

"By giving the vines room, I insure heavy crops of grapes and rich fruit. I tend, prune, &c., with satisfaction; the first with the plough, and a little with the hoe while making the potato crops. The room enables me to gather the fruit with ease, and readily.

"I employ the trellis in cultivating the grape. In all respects it is the best. Our native and such other grapes as I cultivate prefer it. This appendage to the vineyard costs me about five dollars annually per acre, including pruning. I cut down sassafras or cedar trees—say nine and ten inches in diameter—into posts eight feet; point the butt end; put the small end in the ground, ten feet distant; nail on the sides laths about two inches square, just as split from the cypress log, and my trellis is done. My tying (the best I have ever found) is the bear grass, found readily in the woods profusely scattered in spots: shrunk over the fire when green, it becomes a soft, pliable tying. Thus you see I am all economy, and no part of the 'Indian's gun' cost more than it came to."

SUCCESS OF AMERICAN VINEYARDS.

Messrs. Fleet & Starr: Seeing some disquisitions lately in your valuable periodical on the manner of planting the grape vine, I concluded to forward you a few thoughts on that and like matters. Notwithstanding exceptions, (and they made evident in the given cases,) it may be laid down as a rule, that success in any branch of agriculture, as well as in most other pursuits, is the best *prima facie* evidence of right procedure therein; or, that there is an intimate connexion established by Providence between the attainment of any object of enterprise and all the steps that lead thereto. To apply this rule to my vineyards: After some dozen years of culture, I have, most flourishing and prolific, six acres of vines, old and young, part of which (the older) form a continuous canopy, say eight or ten feet high over head, and underneath nothing to intercept the passage of wind, teams, or people; or nothing to be seen underneath but the main stems of the vines, from ten to twenty feet each way, and posts ten feet apart. The planting of all my

vines was on the principle common with my other procedure on the farm in that respect, viz: in reference to the fact of all the vegetable creation having tap and lateral roots, and that both must be sustained in some appropriate way, that the desired end of prolific issue may be attained. Some plants may be called tap-rooted because mainly depending on tap-roots, as cotton, turnips, &c.; others lateral-rooted, because mostly sustained by their lateral roots, as corn, &c. But both kinds of roots must, as a general rule, have their office sustained, or no adequate success will be had in their culture; but, so far from a culture exactly adapted to either, in my experience, I have had desired success in a method common to both: for instance, while I raise turnips by putting manure in drills and bedding thereon, and then planting. I have done the same with corn, and had like success, with this difference only—with turnips, to have the bed raised with an eye to drawing dirt from them in cultivating; and corn, with a hollow rather when planted, except it be in a low or damp location. But it may be laid down as a rule, that no planting or culture should be so deep as to neglect the existence and sustaining of lateral roots near the surface, or near enough thereto for the sun's heat to have its genial influence. So with vines and trees. You even do a violence to their nature to plant or cultivate them too deep, which violence will be revenged, generally, by a small or no yield at all. The general rule for planting fruit trees will aptly apply to that for vines, viz: to plant an inch or so deeper than they stood when growing in the nursery. I say in the nursery, as to vines as well as trees, for I consider (and practise) that grape vines should first be cultivated in the nursery a year or so before eligible for setting out in the vineyard. The Scuppernong, not growing from cuttings, I first root by layers, and then make them well-rooted vines in the nursery ere planting in vineyard, or selling. But other kinds of vines I cultivated first in the nursery by cuttings, often being thickly set in drills three feet apart. By-the-by, fall planting is decidedly most successful for cuttings. Frequent discouragements in vineyard culture arise from attempts to start vineyards with cuttings, and not well *rooted* plants.

And whatever is said of European culture—of short distance apart and humble height, and of servile imitation of foreign modes in our country—certainly the American mode of 10 or 20 feet apart, and say 30, 40, 60, or more, length of branches on scaffolding, would seem to make *an up-hill business* of beginning a vineyard with cuttings. Plants as well as animals are of gigantic growth in America, compared with *eastern size.* And no success has yet been attained, and I predict never will be, by *thwarting* instead of *aiding* nature in vine culture. Hence the reiterated abortive attempts of foreigners to succeed with the vineyard business in our country. All attempts at planting vines very deep, or cutting off upper roots and the like, will generally prove worse than useless trouble in America. All the disturbing of lateral roots of my vines is that of the mere surface ones, by shallow working with cultivators, harrows, and the like, to prevent the undergrowth of anything, and to incorporate all fallen leaves with the soil beneath the canopies, as equivalent to nature's plan of keeping up the fertility of the woods. But, to conclude these hastily written and desultory remarks, I will state briefly the yield of a quarter of an acre of vineyard nearest my house, and managed, *from the start*, according to the above hinted American plan. The kinds of vine are mostly Scuppernong, with some of my Halifax, Norton's V. seedling, and Cunningham, besides; grapes gathered and shaken, (the Scuppernong grapes by holding a large sheet

underneath the canopies, and shaking the branches above with a forked stick, when all ripe ones fall,) to make wines—quantity not calculated precisely, but say several barrels. The following drains upon said quarter were had for more than a month, viz: Visitors daily therein, to pluck the fruit on the advertising terms of 20 cents each entrance, and commutation for companies, (partaking standing on fixtures, to reach the grapes above,) and grapes gathered to carry away at prices of 40 cents per gallon. Frequently 20 or 30 visitors a day; and at one time 60, and at another 95 white persons, besides colored servants, mostly partaking of the fruit of said quarter of an acre. When the 95 had eaten abundantly and retired, some of the company went back to see the change of appearance as to fruit on the canopies, and reported they could not miss the grapes, or was no perceptible alteration as to appearances of branches well loaded everywhere. In short, the calculation is, that from visitations and sales of grapes, and product of wine, this quarter acre yielded at least 50 dollars profit the season, or at rates of the interest on 800 dollars, or more than 3,000 dollars the acre. This statement, to those not conversant with the prodigious bearing qualities of a well managed American vineyard, may appear incredible. But the same statements in other periodicals, as the Cultivator, read in my region, would jeopard my veracity if not true. My list of vines you may see in the November number of the "Albany Cultivator;" which list have the goodness to transfer into your columns, as if for you written. Strain the grape juice through several folds of a woolen blanket, and then add at least two pounds of sugar per gallon, and my word for it, a good wine will be the result; and better for some tastes, at least, than if a fourth of spirits be added, and one pound of sugar per gallon.

In haste, yours, &c.,

SIDNEY WELLER.

BERKLEYVILLE, HALIFAX CO., N. C., *October* 22.

LETTER TO THE HORTICULTURAL SOCIETY.

CINCINNATI, *September* 26, 1845.

MR. PRESIDENT: Upon referring to some memorandums of my father, I find amongst others the following account kept of the produce of his vineyard since 1837. As a number of our members are cultivating the vine, I thought it would be interesting, as it is difficult to obtain a statement of the kind kept minutely for a series of years.

It shows the actual produce, and the certainty of the crop before any other fruit in this latitude, and the difference between the Catawba and Isabella as to the yield and certainty; the Isabella having borne a first rate crop for nine successive years—the Catawba failing occasionally, from rot and the effects of insects.

The vineyard has a southern exposure, fronting on the Ohio river—was planted with rooted plants in 1834, and contained at that time 1775 vines, placed in rows four feet apart, and three feet distant in the row; the ground being previously trenched, and the stones taken out to the depth of two feet.

In the fall of 1837, the first crop was picked, as follows: 164 bushels grapes, from which was made 667 gallons of wine. At this time there were

1,125 Isabella and Cape vines, yielding 113 bushels, making 469 gallons, and 650 Catawba, yielding 51 bushels, making 198 gallons.

1838, vintage,	September 10,	produce	327	gallons.
1839, do	September 5,	produce	440	do
1840, do	September 20,	Isabella	240	do
1840, do	September 20,	Catawba	45	do

This year (1840) most of the Catawba rotted on the vines. From this time there were 2,300 vines—about one-half of each kind.

1841, vintage, September 15, produce	237	gallons Catawba.
1841, vintage, September 15, produce	275	gallons Isabella.
	512	gallons.
1842, vintage, September 12, produce	166	gallons Catawba.
1842, vintage, September 12, produce	319	gallons Isabella.
	485	gallons.
1843, vintage, September 15, produce	250	gallons Catawba.
1843, vintage, September 15, produce	288	gallons Isabella.
	538	gallons.
1844, vintage, September 12, produce	108	gallons Catawba.
1844, vintage, September 12, produce	306	gallons Isabella.
	414	gallons.
1845, vintage, September 9, produce	283	gallons Isabella.
1845, vintage, September 9, produce	349	gallons Catawba.
	632	gallons.

About one eighth of the Catawba grapes were destroyed by bees and other insects, after ripening.

The quantity eaten by three families is not taken into this account.

The ground has always been thoroughly hoed in the spring, and kept free from weeds; never manured until last winter, when the ground was covered, and dug in in the spring; and from the result this season, it would pay well, as the vines are in better condition than they ever were after yielding a heavy crop.

The vines have been trained to stakes, and the bearing wood cut out, after having borne one season, leaving two shoots, trained the same season—one to form the bearing hoop or bow, and the other cut to two eyes, to propagate wood for the next year; the vine never having but the hoop and the two eyes left for fruit each year growing at the same time.

This year the ends of the vines have been nipped and the suckers taken out four different times.

The following estimate I have made from what it has cost this year, and is not far from the actual expense, although the labor has been done by the

hands doing the other work on the farm; and in making wine, extra hands were always employed. By planting cuttings, and preparing the ground by sub-soil ploughing, when it can be done, would lessen the expense. The price is what the wine was sold at from the press the season, and is a low estimate.

Estimate.

2,300 vines, at 6 cents - - - - - -	$138 00
2,300 poles, at 2 cents - - - - - -	46 00
1,000 poles replaced - - - - - -	20 00
Trenching ground and planting - - - -	80 00
Manuring last fall - - - - - -	30 00
Two months' work each year, 9 years - - - -	225 C0
Extra work in making wine - - - - -	150 00
Interest on investment before crop - - - -	15 00
	704 00
Credit by 4,306 gallons wine, at 75 cents - - -	3,229 50
	2,525 50

The expense of cultivation previous to the first crop is not accounted for, nor are the press, casks, &c.; but the actual expense of cultivating an acre of grapes, where persons are hired to attend to other work, would amount to but very little, as but a short time is required to attend to cleaning the vines during the season.

Yours, respectfully,

WM. RESOR.

REPORT ON WINES.

[Report of committee appointed by the Cincinnati Horticultural Society, 1844.]

The Committee on Wines beg leave respectfully to report:

That, in order to fulfil the duty assigned them, of examining the specimens of the wines produced in our neighborhood, they assembled at the house of the president, where all those specimens which had been sent to the society were collected and arranged, and your committee then and there submitted them to the proper investigations, *secundem artem.*

Your committee, although by no means diffident in respect to their own skill and talents in estimating the true character of the articles whose qualities they were called upon to determine, judged it expedient to ask the aid of several German gentlemen, who have been accustomed to judge of the qualities of the European wines to which those of this region bear the strongest resemblance; and, in compliance with this request, Messrs. Brachman, Werk, and Rehfuss attended their session, and politely afforded them the aid of their judgment and experience.

The wines were designated by labels, which referred to sealed descriptions of their ages, owners, &c., and which were not opened until the

judgments respecting them had been pronounced and duly recorded. The subjoined table gives the result of their trial.

Marks and Nos.	Verdict of the judges.	Name.	By whom sent.
C. A. 1837 -	Good - - - -	Catawba - -	J. E. Mottier.
" 1844 -	New, not matured - - -	Do - -	Do
" 1835 -	Very good, resembling old Madeira	Do - -	Do
" 1834 -	Fine, resembling Muscat or Malmsey - - . -	Do - -	Do
" 1843 -	Good for new wine—with age, will be of the best quality - -	Do - -	Do
" 1837 -	Good, high flavored - -	Do - -	Do
" 1838, F.	Superior to any of the previous specimens - - -	Do - -	Dr. Flagg.
" 1831, F.	Good, resembling Hock - -	Do - -	Do
R. H. 1837 -	Good dry wine - - -	Do. R. B. -	J. Resor.

No. 3 -	Good strong wine - - -	1830, Catawba -	Do
No. 7 -	Not American wine - -	Spanish Manzinello -	Do
German label	A good wine, but not the best -	1830, Catawba -	Do
R. F. No. 1 -	Inferior, a foreign wine - -	Old Hock - -	Dr. Rehfuss.
" No. 2 -	Good, about equal to No. 4 -	1839, Catawba -	N. Longworth.
C. A. No. 4 -	Good, about equal to or better than No. 8 - - - -	1837, do -	Do
" No. 6 -	Good—considered by some better than No. 8; by others not so good	1837 do -	Do
" No. 1 -	Inferior to No. 8 - - -	Catawba - -	Do
S. F. 1 -	Very good, resembles Manzinello	Spanish [on skins	S. E. Foote.
N. 60 -	Good Cape wine, very ripe -	Cape, not fermented	N. Longworth.
" 70 -	Very good, resembling Madeira -	Cape, ten years old -	Do
" 50 -	Old wine, but indifferent - -	Lenoir on the skins -	Do
No. 40, N. -	Poor, fermented on the skins -	Ohio grape - -	Do
No. 10 -	Not liked, supposed to have been injured in the bottle - -	Mo., 1841 - -	Do
No. 3, M. -	New and good Catawba - -	–	Do
No. 34, M. C.	Very good Cape - - -	–	Do
No. 37, M. C.	Good, but not equal to the preceding	–	J. E. Mottier.
No. 35, M. -	Good, better than No. 34 - -	–	Do
No. 44. M. C.	New Cape - - - -	–	Do
No. 2, 2d -	Good old wine - - -	–	Do
No. 41, C.	Very good Catawba, resembling Rhenish more than any other -	–	N. Longworth.
No. 1, 2d -	Tolerably good - - -	–	Do
No. 34 -	Very good, old - - -	–	Do
	Do. do. - - -	–	Dr. Smith.
	Good new, not in a suitable state for judgment - -	–	Do

The judgments pronounced and recorded in the foregoing table were as nearly unanimous as can ever be expected among so many judges. It will be seen that several of the specimens were foreign wines, included probably to test the connoisseurship of the committee; it will also be seen that the committee stood the test reputably. The result of the examination is a conviction on the part of the committee that our soil and climate are well adapted to the production of a very fine, delicious wine, and that the

Catawba grape is the species which yields the finest qualities. It will be seen that the greatest number and variety of the specimens examined were from the several vineyards of N. Longworth, esq., who has been longest engaged in the cultivation of the vine, and in perfecting the manufacture of wine. Mr. Mottier and Jacob Resor, esq., who have lately acquired a good reputation in this department of horticulture, were next to Mr. Longworth in the number and variety of specimens furnished. These, with the single specimens of Dr. Flagg, and the two specimens of Dr. Smith, confirm the opinions of the committee, that the pure juice of the grape, when judiciously managed, will furnish the finest kind of wine, without any addition or mixture whatever; that no saccharine addition is necessary to give it sufficient body to keep for any length of time in this climate. In confirmation of this opinion, we would state that two of our German friends who were present informed us that they had taken, on different occasions, specimens of the wine of this county to Germany, and submitted them to the judgment of various connoisseurs in that country, by whom they were highly approved; the principal or only objection being that they were too strong to compare with the fine kinds of the lightest German wines. A taste for the wines of this region appears to be well established, since all that can be produced finds a ready market at good prices; and the committee are of opinion that the period is not distant when the wines of the Ohio will enjoy a celebrity equal to those of the Rhine.

CULTURE OF THE GRAPE.

As public attention, at the present time, seems to be somewhat enlisted in the culture of the grape, and as its success is pretty well established in the vicinity of Cincinnati, where it is rapidly extending, a brief sketch of the most approved mode of establishing a vineyard may be acceptable to some of your readers.

The first step, then, is the preparation of the ground. The sides or tops of limestone hills are generally chosen for the location, where the water runs off readily. South and southeastern exposures are the best in this climate. Three modes of preparing the ground are usually adopted here. The first consists merely in deep ploughing, with a common plough, as for potatoes, and making the surface fine and mellow with the harrow. The second method goes one step farther, and a second furrow is cut in the bottom of the first; in the bottom of the second furrow a sub soil plough is run, which breaks the ground, altogether, to the depth of sixteen or eighteen inches; it is then harrowed and prepared as in the first. The third method is by thoroughly trenching with the spade, to the depth of not less than two feet. If the hill-side is steep, (say at an elevation of twenty or thirty degrees with the horizon,) terraces are also raised from two to four feet in height, and extending up the hill from twenty to sixty feet each, according

to the acclivity of the surface. By this last mode, the top soil is all thrown into the bottom of the trenches, and the sub soil, which is generally clayey, thrown upon the top, and left sufficiently smooth for planting. Where stones are found in the soil, they are thrown out on the surface, as the trenching progresses up the hill, and if in sufficient quantity, are laid up in walls to support the terraces. The terraces are made to run horizontally along the hill side, or nearly so, with an open ditch, for a drain, at the upper edge of each terrace, and a similar horizontal ditch as often as once in eighty or a hundred feet, where the ground is not terraced. These drains should lead to the lowest point in the vineyard, where a suitable drain should be constructed down the hill to carry off the surplus water in heavy showers, and may be covered like a culvert, or left open. In each case the vines are planted in rows, four feet apart if to be worked with the hoe and spade, and from five to six feet if to be worked with the plough or cultivator, and should always run horizontally with the terraces and drains. The distance between the vines in the row varies from two and a half to four feet, according to the mode of training which is to be adopted.

Cuttings of the vine, with three or four eyes, are sometimes planted, at proper distances, in the vineyard; but the usual practice is, to plant them first in a nursery, in rows, about eighteen inches apart, and from four to six in a row, to strike root; here they are to be well cultivated, and allowed to grow one or two years, when they are taken up in the spring and planted out in the vineyard. The fourth year from the cuttings, (that is, after they have had three summers' growth—two in the nursery and one in the vineyard,) they may be allowed to bear a full crop, or nearly as much as they ever should be allowed to bear thereafter; which is about one-fourth of a peck of grapes to each vine. One acre of ground, planted six feet by three apart, will contain about twenty-four hundred vines; consequently, will yield about one hundred and fifty bushels of well-assorted grapes, which will make three hundred gallons of wine—sometimes a little more. An acre of good ground, well trenched, and planted with Catawba vines, after it has acquired six or seven years' growth, may be made to yield a much greater quantity; and some small vineyards below Cincinnati, on the hills of the Ohio river, have produced at the rate of eight hundred gallons per acre; but the vines were planted four feet each way, making twenty-six hundred and forty vines to the acre; but the proprietor admitted that his vines were injured by over-bearing, and that his wine was inferior in quality when allowed to produce that quantity.

I give three hundred gallons as the full average quantity of wine made to the acre in the neighborhood of Cincinnati. Of course, much variation will depend upon the manner of establishing a vineyard, and its subsequent treatment.

The comparative merits of the different modes of preparing the ground for a vineyard cannot, as yet, be settled by experience in this part of the country, as the oldest vineyard, I believe, has not been established more than twelve or thirteen years. Vineyards planted at Vevay, in Indiana, by the Swiss, merely on deeply ploughed ground, failed in fifteen years. When the ground is ploughed eighteen inches deep, it may bear tolerably well for twenty years; but a vineyard planted on ground well trenched two feet deep, and properly drained and cultivated, may be expected to last fifty or one hundred years—perhaps more. The crop, also, is much more cer-

tain when the ground is well trenched, not being so liable to suffer from droughts or rainy seasons.

The advantages of deep trenching have become so apparent to those who have had the most experience, that nearly all who can afford it are now preparing their ground in this manner, although done at an expense varying from eighty to one hundred and twenty-five dollars per acre, according to the character of the ground. This, with the addition of twenty-four hundred vines, at sixty dollars per thousand for one year old vines, (the customary price in this market,) with the cost of planting, will make the expense of one acre, exclusive of land, stakes, &c., at least three hundred dollars, or, without trenching, about two hundred.

S. MOSHER.

From the Boston Cultivator.

A DAY AT THE REYBOLDS' IN PEACH HARVEST.

Desirous of affording our readers the means of forming some idea of the magnitude and importance of the peach business of Delaware, we lay before them the details of "A day spent at the Reybolds' in peach harvest."

We took passage from Philadelphia by the steamer Pioneer, at Arch street wharf, at 7 o'clock on the morning of the 29th August, (Reybold's wharf adjoining being full to overflowing with his empty baskets in transitu,) passing the steamer Napoleon, which had arrived at the railroad wharf on the Camden shore, and was discharging her lading of 3,000 baskets of Reybold peaches for the New York market. During the passage to Delaware City we were continually passing boats of different descriptions loaded with peaches for the Philadelphia market; reaching the wharf at 11 o'clock, 40 miles below Philadelphia, where it was with difficulty that we could pass along it, for the rows of baskets of Reybolds' peaches, three tiers in height, and extending about one hundred yards in length, flanked with carriages, from the six-ox and six-mule wagons, counting their 125 baskets each, to the single-horse cart or dearborn, with its score or two, awaiting their turn for unloading; reloading with empty baskets and driving furiously back for more—a scene which bade defiance to imagination.

Here we found the Reybolds loading a sloop, which departed for Philadelphia with 1,230 baskets, only to make room for the Cohansey steamer, on board which were placed 1,000 baskets more; and then they began to prepare the evening's loading for the Napoleon, that had returned from Philadelphia during the day, on which were put 1,700 baskets from the orchards of Messrs. John, Philip, jr., William, and Barney Reybold, when she proceeded to the wharf of Major Reybold, which is situated in the midst of his orchards, to complete her loading—another 1,490 baskets—starting for Philadelphia so as to be again in the market before daylight next morning, with a total of 3,190 baskets.

The details of this day's shipment, therefore, are as follows:

On board the sloop - - - - -	1,230 baskets.
On the steamer Cohansey - - - -	1,000
On the steamer Napoleon - - - -	3,190
Total baskets - - - - -	5,420

from the Reybold peach orchards only. These all reached their destination before daylight next morning, consigned to Mr. Anthony Reybold, by whom they were disposed of before 11 o'clock, at from 16 to 31 cents per basket, containing about 3½ pecks each.

From the books of Major Reybold and his sons was ascertained the quantity of peaches sent to market to the 29th August, inclusive, viz:

Major Reybold, from his Maryland and Delaware orchards	31,145 baskets.
John Reybold	13,300
Philip Reybold, jr.	6,000
William Reybold	5,699
Barney Reybold	7,200
Total number of baskets	63,334

Number of baskets employed for transit	40 to 50,000
Number of acres of orcharding	1,090
Number of trees planted in orchards	117,720

Business detaining us in that part of the country, we returned to Delaware City on the 31st, and found the Reybolds loading two large steamboats at the wharf—the "Napoleon" for Philadelphia, and the "Mutual Safety" for New York direct by sea; the latter of 700 tons burden, leaving with 3,581 baskets on board; the former completing the shipment for that day, a total of 4,075 baskets, having taken, the day before, her usual loading of near 3,000. Here we saw three steamers loading with peaches at the same time, while the empty return baskets had numbered 16,000 within the last 24 hours. Major Reybold has it in contemplation to start a large steamer with peaches direct to Boston! Success attend him!

In conclusion, we would add, Mr. Philip Reybold, jr. is extensively engaged in the nursery business, more particularly in the raising of peach trees, of which he has from 60,000 to 80,000, 5 feet high and 2½ inches in circumference, from the seed the present season; and, from the facilities which he enjoys, as well as the peculiar care and attention employed, those requiring the very finest varieties, so as to form successional orchards, may depend upon a supply of trees true to character and of "most magnificent proportions." It is worthy of remark that the largest peach ever raised in England, by the most careful culture, measured 12 inches in circumference, while in the orchards of the Reybolds, the present year, one has been found to measure 11½ inches in circumference, and hundreds from 10 to 11, in the open ground, and the largest crop, perhaps, on record—the third in succession.

At the conclusion of the harvest, we will endeavor to present our readers with the sum total of peaches sent to market from Newcastle the present season.

JAMES PEDDER.

PHILADELPHIA, *September* 1, 1845.

From the New York Farmer and Mechanic.

NEW YORK FARMERS' CLUB—TUESDAY, *May* 20, 1845.

Cheever Newhall, esquire, vice president of the Massachusetts Horticultural Society, in the chair.

PEACH TREES.

Mr. Wakeman.—I present a paper on the peach tree, from my worthy friend George F. Hopkins. The well known havoc made by its enemies upon that delicious fruit tree renders every suggestion for its defence and conservation most acceptable. The letter recommends tobacco tied around the bodies, and the application of alkalies, of whale oil, and of blacksmiths' cinders, to the roots. I noticed a case in Philadelphia of a tree on the roots of which hot water had been poured, and soot and lime applied, and the tree bore good fruit every year for twenty years. I refer to Mr. DePeyster's statement, at a former meeting, of his success in consequence of placing anthracite coal ashes around the roots of peach trees.

Col. E. Clark.—Lime recently burnt, placed at the root of a tree, has the effect of killing worms; many of them are dissolved, when in contact with the lime; being moist, they afford the means of their dissolution. Common tansey planted next to the roots, is said to keep off the worms. When lime is sprinkled at the root, it must be wet either by rain or by hand. I know of no better remedy.

Mr. Wakeman.—I ought to mention that the tree in Philadelphia was annually whitewashed.

Ethan Campbell, esq.—I applied quick-lime to the roots of ten peach trees, annually, since 1839, and those trees are healthy. I planted tansey at the roots of twenty peach trees: they were not attacked by worms. The worm bores a hole through the bark at the edge of the ground; its eggs are hatched in June, and I have taken thirty worms out of the bottom of a single tree. The trees protected by tansey give me full crops of fruit (and fine, too) annually. Ten peach trees, to which I applied nothing, all died the third year.

Colonel Travers.—I planted on my farm, in Jersey, 900 peach trees. I treated them every way—ashes, lime; I cleared the roots—and had 120 left. One near my home I cultivated as I would a cabbage, leaving no grass or weeds near it; that one is a healthy and vigorous fruit bearer—*cultivation does that for it.* The tree, and all plants, must, like animals, have good and proper food. The grub-worm does not mind ashes, or lime, or salt—he will crawl out of it; and I have tried, by wrapping them in these substances, to kill them, and they don't mind it. I tried it on bots taken alive from a dead horse; the bots were not killed by it, nor by any of the articles given to a horse as remedies for bots. This animal does not die, either in or out of a horse, by being enveloped in the articles. As to the peach tree, I wrapped a bandage and a mat over that, around the body of the tree, just under the forking of the branches, yet the worm ate down to the ground. All the remedies applied at the roots of the trees were, I have no doubt, useful to the soil; they invigorate the tree, but they do not kill worms.

Mr. Wakeman.—There may be some ingredient in certain soils, which, mixed with soot, ashes, or lime, may be disagreeable to the worm. At all events, we are looking for useful results in all our inquiries. Contradiction is itself often highly useful, in bringing out the truth which we desire.

Chairman.—I have adopted the following plan for my peach trees, during the last four or five years. I bore a piece of sheet lead, about six or seven

inches wide, and place around the bottoms of the trees, putting the lower edge of the lead about an inch in the ground. I then fill the space between the tree and the lead with anthracite or wood ashes, or with sand. My trees so treated are healthy and bear well.

Colonel Travers.—Mr. Woolsey put wooden boxes around the roots of his peach trees, and filled the space between the box and the tree with charcoal; these trees, he says, lived twenty years.

Chairman.—Mr. Vose takes tarred paper, puts it around the tree, six, eight, or ten inches above the ground; takes it off in the autumn; he also gives his trees special attention; his peaches are excellent. I applied the lead plan to at least forty of my peach trees.

Mr. Townsend, of Astoria.—Being on a visit to a friend in Norfolk street, in this city, last summer, I was struck with the fine healthy look of a peach tree in the yard. On inquiry, the lady of the house told me that every spring she poured a teakettle of hot water upon the trunk of the tree, which ran down to the ground. This had been done for fifteen years, and the fruit was always good.

Colonel Clark.—I have no doubt that lime in the boxes would have a good effect; when moistened, it is powerful enough to affect the hand, and will destroy insects.

Ethan Campbell.—Lime would certainly prevent the approach of insects, I apprehend, and prevent its depositing its eggs. I recommend a sprinkling of lime once a week around the roots of peach trees from the beginning of April.

Oliver Smith.—Those insects which injure fruit deposite their eggs in the fruit itself. Lime does not reach or prevent that. When the insect is hatched, it then descends the tree and enters the ground.

Colonel Clark.—The curculio preys on pear, plum, and some other trees, but does not touch the peach. The worm which destroys enters at the bottom of the peach trees, and bores between the bark and the wood.

From the Southwestern Farmer, of July.

CULTIVATION OF FRUIT AT THE SOUTH.

We will now examine into the cost, and look at what might be reasonably counted on, as to the profit of this culture.

Fruit trees would cost, on an average, delivered on the farm, we will say 40 cents each. If planted 25 feet apart each way, 69 trees will be required, which are worth $27 60. The cost of cultivation, interest, and rent of land, will be paid for the first three years by the corn crop, so many hands not being required, and a profit realized by the sale of fruit, as well as the use of hands for the winter months at least. We will set this down, though, at only a stand off, and begin when the fruit is the only crop.

35 acres land, worth say $10 00 per acre	=$350,	interest 8 per ct.,	$28 00
Fruit trees - - 27 60 "	828,	"	66 24
A pair of choice mules and wagon	300,	"	24 00
Hire of six hands, $150 each	900,	"	72 00
Food, clothing, doctor's bills, taxes	240,	"	19 20
Ploughs, tools, &c., wear of gear, mules, &c.	100,	"	8 00
Making, in all - - -	$2,718	"	217 44

To meet this expense, and to pay interest, we will assume the following very moderate yields and prices from sales, hiring, &c.:

By 1 bushel of fruit only from each tree of the best, at only $1	$2,070 00
Food for hogs, (the selected fruit only gathered,) at $5 per acre	150 00
Hire from hands for the months of November, December, January, and February, at $10 per month - - -	240 00
Making a total cash return of	$2,460 00

Our object is to be entirely within the mark; and we think we have placed our calculation far within it. We firmly believe that six hands, &c., as above, can keep up the fertility of land, can make enough corn and meat to feed themselves, can be spared for four months at other work, and can then sell gross amount of $600 per hand.

APPENDIX No. 17.

ON MUSTARD.

From the Ohio Cultivator.

MUSTARD CROP IN OHIO—PRICES OFFERED FOR THE SEED IN PHILADELPHIA.

We have made inquiries respecting the success of our friends who attempted the cultivation of mustard seed in this State, the present season, and we learn that although some failed entirely, owing to the frosts and drought, the majority have succeeded remarkably well, considering the unfavorableness of the season, and their want of experience in the business. The following are the principal lots:

Mr. Parmelee, Duncan's Falls - - -	27 acres.
Mr. Buckingham, Putnam - - - -	9 "
Mr. Ely, Chillicothe - - - - -	15 "
Mr. Myers, Canton - - - - -	7 "
Three or four smaller lots, say - - -	12 "

Making in all seventy acres; and there may be other lots in the State, of which we have not heard. Mr. Parmelee's crop is about as good as last year—say fourteen bushels per acre. Mr. Buckingham's is nearly as good. Mr. Ely's, and the smaller lots, were somewhat injured; we have not learned the amount of the yield; probably not over seven to ten bushels per acre. This will give, for the whole amount, 700 bushels.

We have just received a letter from Messrs. C. J. Fell & Co., of Philadelphia, in answer to one from us, in which they generously say, that although the market price for seed is not well established, (and it may range lower than last year,) yet, inasmuch as they may have been instrumental in inducing some Ohio farmers to engage in its cultivation with the expectation that the same price would be given this year that was paid Mr. Parmelee last year, they now offer to pay that price (eight cents per pound in cash) for all Ohio seed that may be sent to them *of as good quality* (as heavy and clean) *as was Mr. Parmelee's last year;* to arrive at Philadelphia not later than the first of November. For seed of a less perfect quality they will pay a proportionate price; and to avoid any dissatisfaction, they offer to let the weigh-master send us samples of the lots that arrive, and have us compare with seed of Mr. Parmelee's last year's crop, and say what deduction ought to be made in the price.

The seed should be packed in good strong flour barrels, and shipped by way of Pittsburg. The cost of transportation from Pittsburg to Philadelphia is sixty cents per hundred weight.

The Messrs. Fell also inform us that they have shipped for us a box of small canisters of mustard, manufactured from Ohio seed, which we may distribute to persons engaged in its cultivation, and such others as we see fit. We will do so, with pleasure.

From the Ohio Cultivator.

SALES OF OHIO MUSTARD SEED.

Statement of the amount of Ohio mustard seed purchased by C. J. Fell & Brother, of Philadelphia, previous to 1st December, 1845; furnished at the request of the editor of the Ohio Cultivator:

R. Prouty's crop, Morgan county,	40 bags,	4,771	lbs. at	8 cents	$301 27
J. H. Seeley, " "	20 bbls.	3,580	"	8 "	286 40
H. M. Myers, Stark county,	7 "	1,470	"	8 "	103 29
One lot Muskingum co., (inferior)	17 "	3,056	"	7½ "	229 20
Sundry small lots	17 "	2,814	"	8 "	225 16
Purch'd of Goodhue & Co., N. Y.*	42 "	7,535	"	7 "	527 45
J. H. Parmelee's crop, Muskingum county, purchased through our agents, Adams, Cushman, & Co., New York	82 "	15,883	"	7 "	997 01
Total - -	225	39,109			2,669 78

This would make, in all, 760 bushels, of 52 lbs. each.

PHILADELPHIA, *December*, 1845.

DEAR SIR: In compliance with your request, we hand you the above account of our purchases of Ohio brown mustard seed, of crop of 1845, up to 1st inst. There are several lots we are advised of on the way, not yet received. The quality of several of the above lots was much inferior to Mr. Parmelee's last year's crop; but, in a market with a limited supply, we asked no deduction, except in one case, the grower preferring to send sample before sending his seed, to know what deduction from our published offer we would expect. In that case we claimed one-half cent per pound, which was satisfactory to the grower, and thus we have not been compelled to trouble you with samples for you to assess their value. We would, however, recommend farmers to clean their lands more thoroughly, and to deliver their seed in good order, fully ripened; as, in a full market, many of the crops we have taken as *prime* would fall below that quality, and of course would have to be sold at a reduction from market value of truly prime seed.

We regret that all your farmers did not take advantage of our offer, made through your paper of September 15th, but sent their crops to other markets, two of which you will observe we have purchased in New York at 7 cents, New York price. We felt disappointed that our old "pioneer," Mr. Parmelee, should not have brought his crop direct to us and obtained Philadelphia price, as we expected from the tenor of a letter we had from him in August last, that his crop would have been better than last year; as he then informed us "that he had the same land again planted with mustard seed, and had expended $250 extra expenses in cultivating it," and that "the gathering of his crop was a *four weeks' job for twenty men.*" We expected that the result of such a crop would have shown our farmers that American soil and American labor will produce profitably a crop of brown

* This seed was raised by Thomas Few, Muskingum county.—*Ed. Ohio Cultivator.*

mustard seed. You will observe that we have *only* the product of his *brown* seed. We learn that a portion of his 27 acres was planted with *yellow* or English seed, which explains why his crop has fallen off from last season. Can you learn and inform us of the result of his yellow seed? To what cause may it be attributed that he was at so great expense over that incurred by his neighbors in cultivating and harvesting the crop? We suppose probably the yellow seed was the cause; or, perhaps, the planting the seed for two years on the same land. If this latter is the case, we should recommend no farmer to do it, for they not only incur a large amount of labor, but produce a seed much inferior to that raised on land planted with it for the first time; as Mr. P.'s crop was much inferior this year to any other crop we have purchased.

We had intended to have given you the number of acres planted by each person we have purchased seed from, but we found we could not obtain it, and as the spring was so unfavorable to all crops, no certain data could be obtained from it.

Very respectfully, yours, &c.,

C. J. FELL & BRO.

M. B. Bateham, Esq.

Remarks.—We have not room nor time at present, but in our next, or the following number, we shall give some account of Mr. Parmelee's operations, and we fear it will be our duty to show that his statements to Messrs. Fell & Bro., and to others, have not all been in strict conformity with truth and fairness. It seems to have been his desire, from the first, to dissuade all others from engaging in the culture of this crop, in order that their competition might not tend to reduce his profits. We have little sympathy with such a spirit among farmers.—*Ed.*

—

OHIO MUSTARD SEED CROP—ITS CULTURE.

The amount of brown mustard seed raised in this State the past season we should judge was over 1,000 bushels. Of this we have before shown that Messrs. Fell & Brother, of Philadelphia, purchased 760 bushels, for which they paid, in cash, $2,669 78. These gentlemen were prepared to have taken a larger quantity at the same rate, had it been offered to them. The price paid by them for good seed, sent direct from Ohio, was eight cents per pound. Some that was sent to the New York market they bought at seven cents—(the average weight per bushel is 52 pounds.) Quite a number of those who attempted its culture last year were unsuccessful, owing to the remarkable character of the season, and their want of experience. We presume a much larger quantity will be raised the coming season; but we are not sufficiently informed as to the extent of the demand at the east, to judge whether any material reduction of price is to be anticipated from this increase of supply. We believe, however, that large quantities of the seed are annually imported for the Boston and New York manufacturers, and that no fears need be entertained of glutting the markets at present; though it is possible that a slight reduction of price may have to be submitted to hereafter.

In fulfilling our promise to give full directions respecting the culture of mustard seed, we offer, first, the following experiments and observations by

a very intelligent young farmer of Muskingum county, who has had one year's experience in the business, and has derived some little advantage from a knowledge of the practice of Mr. Parmelee, who resides but a few miles distant. We expect to be able next month to give a detailed account of Mr. Parmelee's mode of culture, written by himself.

On the cultivation of mustard seed.

Friend Bateham: In accordance with your request and my promise, made some time since, I will now give you an account of my last year's experiment in the culture of brown mustard seed, together with such observations and suggestions as I think may prove serviceable to those who may desire information on this subject.

The field that I sowed with this crop last spring was 10 acres; soil, a light rich, sandy loam, excepting about one acre, which was clayey—the previous crop wheat. On one-half of this field I applied, early in the spring, 100 two-horse wagon loads of manure, and 600 sheep had been kept nightly on the lot for a month previous, so that it was well enriched before ploughing.

By the 9th of April the soil was ploughed, harrowed, and bushed smooth, ready for sowing. I then with a small hoe made drills or trenches one inch deep and two wide, two feet apart; then, with a cup of seed in one hand, I sowed it by taking as much at a time as could be held between the thumb and finger, and scattering it along the drill, as near as I could judge, one inch apart. (I used about a quart of seed to the acre.) A little practice enabled me to drop the seed quite regularly, and almost as fast as a horse would naturally walk before the plough, or at the rate of two and a half or three acres per day. The seed was covered to the depth of one quarter to one-half inch, by having a boy draw a brush over the drills.

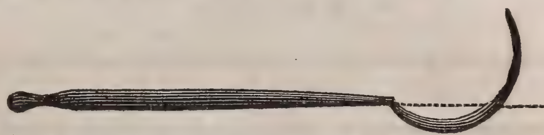
The weather being very dry, and also cold, the plants did not make their appearance till 10 or 12 days after sowing; they then grew very rapidly for about two weeks, when the drought again stopped them for near a month. During this time the ground was kept clean of weeds by hoe and hand. The first time cleaning was 12 days' work. To have done it in the best manner would have taken 18 days.

Being somewhat at a loss to know whether to thin my plants or not, I rode down to Mr. Parmelee's great field for information. I there found that his plants were at least a week ahead of mine in growth, and that they were standing more than twice as thick in the rows. He had also made every alternate row one foot apart instead of two, so that he had about three times as many plants as I had to the same ground.

After the first cleaning I tried using a shovel plough, but it covered weeds and plants together. I then made a small cultivator, having five teeth, like little shovels, the size of a man's hand; this was the thing required, as it cut off the weeds and mellowed the soil without disturbing the plants. With this I went over the field three times in two weeks; then followed with a shovel plough, twice to a row, with boys to pull weeds out of the rows and uncover any plants that got buried. This left the field clear of weeds, and finished the work till harvest.

Not being quite certain as to the proper time or best manner of harvesting the crop, I again went to Mr. Parmelee for information; I there found that he delayed cutting till the pods were dead-ripe and the stalks nearly

dry. It was then cut with sickles—[the kind with *smooth edges*, sometimes called grass sickles in this country—Editor]—and laid in small heaps for several days, to dry. I waited till my crop became sufficiently ripe, and had some knives or sickles made for the purpose, of a form that I found was quite an improvement on those sold at the shops. I give you a rough drawing of one, which will explain it.



The handle is two feet in length, and of size to suit the hand. The blade resembles a sickle, but is less curved. The edge forms a regular half circle, say 12 inches in diameter, and the shank is so formed that a straight line drawn lengthwise of the handle would strike the edge at the middle of the curve, (as shown by the dots in the above cut;) by this means, when using the knife, it is drawn with a sloping cut, instead of square across the stalks, as is usually the case with the common sickle, thus making easier work and causing less jar and waste of seed in cutting. At first, I cut during all the working hours of the day; but perceiving that the seed shelled out much worse after the dew was off than before, I hired half a dozen hands to work for me at six and a quarter cents per hour each morning, from daylight till the dew was off, during which time we cut about an acre each morning—costing about $1 50. The cutting was done from the 1st to the 10th of August.

After leaving the stalks in the field till perfectly dry, I hauled them to the threshing floor on a sled, having a frame on top covered with canvass, 14 feet long and 12 feet wide, so as to catch the seed which shelled out. The threshing floor consisted of canvass, 12 feet wide and 20 feet long, surrounded on three sides with a strip of brown muslin, two yards wide, (supported by stakes.) At the open end of this floor a sufficient number of sheets were spread to contain the stalks as brought from the field. In threshing, the stalks were laid head to head, in two rows along the floor, 8 to 10 inches thick, then beaten with green hickory poles, 10 or 12 feet long, (we found them better than flails,) till free from pods and seed. Two men threshed in this way, and raked off the coarse chaff, as fast as a man and two boys brought the stalks on the sled, the distance varying from 10 to 40 rods. We threshed in a week the product of the field, amounting to about 50 bushels. After taking off the coarse chaff, which was easily done with a common rake, the seed was spread on a dry floor, where it lay for a month, being stirred three or four times a week to facilitate its drying; (the chaff and dust which remain prevent it from heating or becoming mildewed.) When thoroughly dried, I cleaned the seed with a common fanning mill, passing it through twice, and the tailings three or four times.

Observations.—The improvements that have been suggested to my mind by this experiment, are the following:

1st. That the crop should be sown on sandy bottom soil, which is mellow and not liable to suffer from drought; and sufficiently rich to afford nourishment to the plant and seed without the application of manure, as I have discovered that manure has a tendency to cause an excessive growth of stalks, with but little seed.

2d. That it is better to have the rows arranged as Mr. Parmelee does—the spaces alternately 1 foot and 2 feet wide; and the seeds should not be dropped in a single line or row in the drills, but scattered along so that the young plants cover two or three inches in width in each row, thus:

××

2 feet space.

××

1 foot space.

××

This will require about two quarts or three and a half pounds of seed per acre. Standing thus thickly, the stalks will be smaller and shorter than when thin, but a greater amount of seed will be obtained from the ground without any additional labor.

3d. It should be sown as early in the spring as the ground can be got in good order. Spring frosts will not injure the plants, and an early start will do much to protect them against injury from drought.

4th. The utmost attention must be given to killing the weeds as soon as they make their appearance, and keeping them out of the crop during its growth; otherwise the seeds of weeds will become mixed with the mustard seed, and greatly injure its value.

5th. After harvesting the crop, the ground should be thorougly harrowed, which will cause the shelled seeds to vegetate. The plants will grow till frosts, when sheep should be turned in to eat them off. If this is not done, the mustard will be troublesome to any succeeding crop; and even with this precaution, some will appear the next year.

Yours, &c.,

PHILE.

PUTNAM, O., *January* 22, 1846.

—

MR. PARMELEE'S STATEMENTS EXAMINED.

In our January number we intimated that, in our opinion, some of Mr. Parmelee's statements in regard to the culture and sale of his mustard seed have not been in strict conformity with truth and fairness. We greatly dislike to have any thing to do with personal disputes and accusations—it too much resembles the conduct of partisan editors to suit our taste; but, in the present case, justice to honorable friends, to ourselves, and to a large number of our readers, seems to demand a few words from us in reply to statements made by Mr. Parmelee. Let us hear them.

The first is a communication in the Zanesville Gazette, as follows:

Messrs. PARKE & BENNETT: Having observed in a recent number of your paper, and in others, notices respecting the cultivation of mustard, the tendency of which seems to be to get up a mania on this small article amongst cultivators, and to tempt to disastrous enterprise, I think it not amiss, for one, to hand in to you my experience in that way the last season.

I planted twenty-eight acres with brown, and two acres with white mus-

tard seed. Of the former, the yield was 305 bushels, and of the latter, 15 bushels; in all, 320 bushels from 30 acres.

The expense of the crop, delivered in New York, was $1,089. For 289 bushels I received $1,117. The article being plenty, owing to a great influx of foreign seed, and most of it very beautiful and of superior quality, I was obliged to submit to a reduction of one cent per pound from the price obtained last year. For the white mustard seed there was no demand. One cultivator from the northern part of New York, with a large lot of some hundred bushels of white mustard seed, and a beautiful article, could not effect a sale of the whole at five cents per pound, which would be at the rate of two dollars and fifty cents per bushel.

Comparatively, I consider the result in my own case fortunate, as several undertakings of the same kind around me proved entire failures; owing, I judge, to the neglect of seasonable and thorough tillage.

I have no doubt but the farmer who should apply the same labor in the careful drilling and hoeing of wheat, upon the same land, which he would find it necessary to expend upon the same number of acres of mustard, would find himself much better compensated.

J. H. PARMELEE.

Duncan's Falls, *November* 28, 1845.

The next is an extract of a letter written by Mr. Parmelee to Messrs. C. J. Fell & Brother, of Philadelphia, in August last, inquiring whether they wish to purchase his crop of seed. After stating that the quality of the crop is about the same as last year, or superior to it, he says:

"Appropos, while I write—and perhaps you will doubt it—here comes an agent from a house in Boston, proposing to buy my crop. He will give me eight cents per pound, less the cost of transportation to Philadelphia. I told him that, as we had some dealings, I preferred to sell to you, and that perhaps you were expecting the offer; and that I thought you would give me half a cent more a pound for an article that you know to be well saved, and not likely to sweat and heat. I want that much more to compensate me for extra trouble on account of the season. * * * He will call again. It may not be amiss to say, that the ingathering of my crop is a four-weeks' job for 20 men, and three weeks afterwards a man must be employed to shovel it up thoroughly, every day, as it lays in the chaff."

The letter of which the foregoing is a part is the one to which allusion is made by Messrs. Fell & Brother, in their communication published in our paper on the first of the past month. A full copy of the original has been furnished us, with a number of others relating to the same subject, by the Messrs. Fell, at our request.

This letter and the article from the Gazette we think are characteristic of their author. They are evidently dictated by the same spirit that induced him, a year ago, to complain bitterly of the Messrs. Fell for allowing any thing to be published respecting his large and profitable crop of mustard seed, and also of us for giving information respecting the mode of culture, &c., through the columns of our paper; thereby inducing a number of others to compete with him in the production of an article for which our country has hitherto been, and is still, mainly dependant on Europe! Let us now briefly examine one or two of his statements:

He says, in the Gazette, that the yield of his recent crop of brown seed was 305 bushels, and that for 289 bushels he received $1,117. Now, by

referring to the table of Messrs. Fell & Brother in our paper of last month, it will be seen that they paid him, through their agent in New York, for 15,843 pounds, (305½ bushels,) at seven cents per pound. (This would amount to $1,112; not $997, as stated erroneously in the table.) We have also a copy of the letter of the agent in New York, showing that the whole lot (82 barrels) of Mr. P.'s brown seed was purchased by him and shipped to Philadelphia.

Again: He says he was obliged to submit to the reduction of one cent per pound on the previous year's price, (8 cents,) owing to the article being plenty, and a great influx of foreign seed. This is sheer *gammon*, and contrasts finely with the story of the Boston agent offering him eight cents per pound. Besides, our readers are all aware that Messrs. Fell & Brother made a standing offer, through our columns, of eight cents per pound for all good Ohio seed that might be sent, if shipped direct to Philadelphia; and the only reason why he and one or two others were obliged to accept of a lower price was, *because they chose not to comply with this liberal offer, but took their seed to the New York market, and, after trying in vain to obtain a higher or as high price for it there, offered to sell it to the Messrs. Fell at the price offered by them in Ohio;* but, like high-minded and honorable men, as they are, they very properly told them, since they had not seen fit to comply with their offer, but had taken their goods to other markets, they might sell them in those markets for whatever was then and there the market price. Another reason, we are informed, why Mr. P. did not receive a higher price for his seed, was, its quality was much inferior to his previous year's crop; part of it being unripe, and a part of it sprouted. So far from an unusual influx of foreign seed having caused a decline of price, it will be seen, on referring to our paper of January 1, the Messrs. Fell expressly declare that the supply in market was limited!

We come now to the extraordinary statement, that "the ingathering of his crop was a four-weeks' job for 20 men." To show how much truth there is in this, it is only necessary for us to say that we have recently seen and conversed with several of the men who were in his employ during the whole time, and they informed us that 20 men were only employed for 10 or 11 days, then 12 to 16 men for 9 or 10 days, then 4 men for 5 or 6 days in raking and shovelling the seed; making in all about 380 days' work, or 100 less than stated by Mr. P. Then, too, it remains to be shown what kind of days' work these were. We learn that the laborers were all Germans, who reside at Taylorsville, seven miles distant from the mustard field; that they had to row in a boat that distance down the river, and back, each morning and evening, so that their usual time of commencing labor was 8 o'clock, and of leaving, 4 to 5 o'clock; thus losing, as all must perceive, the best portions of summer days for labor. They were paid at the rate of 50 cents per day, dinners found, or 56 cents without dinners.

APPENDIX No. 18.

ON THE CULTURE OF THE MADIA SATIVA, A NEW OLEAGINOUS PLANT.

[Translated from the Journal des Connaisances Usuelles et Pratiques for 1841, by E. Goodrich Smith, of the Patent Office.]

We reply to the question addressed to us on the subject of the usefulness of the *madia sativa*, by the following note:

The plant called *madia sativa* is a native of Chili. It was formerly known under the name of *madi;* it belongs to the dycotyledonous plants, with corymbiferous flowers, and of the class and order *diognesia polygamia superflue.* There are three species noticed, which are probably only varieties of the same type, viz: the *madia sativa*, the *madia mellosa*, or wild madia, and the *madia viscosa.* This plant has been cultivated from time immemorial, in Chili, for the sake of its oil, which, in the preparation of food and for economical purposes, rivals the olive oil, although it has a less agreeable taste than this latter.

The root of the plant is a tap root, whitish; the stalk is herbaceous, fibrous, branching, about the height of a metre to a metre and 90 centimetres; it is furnished with numerous alternate leaves, *linear lanceolate*, pointed, very perfect, from 10 to 15 centimetres in length, resembling those of the rose laurel—of a deep green, covered, as well as the stalk and branches, with short, whitish, coarse hairs; the flowers are yellow, nearly sessile, aggregate at the extremity of the branches, or in junction of the leaves to the stem; the calyx is spherical, egg-shaped, hairy, with small linear leaves; the flowers are numerous, hermaphrodites, three-toothed; the seeds about a centimetre and a half in length, covered with a blackish thin skin, and which becomes gray on being dried, convex on one side and flattened on the other; in this covering there is a bitter principle, which imparts to the oil of this seed a disagreeable taste for persons not accustomed to it.

The *madia* imported from Chili by the Jesuit Father Feuillé had been already cultivated in Europe about the year 1760; but its culture was abandoned, doubtless because at that period the plants which required careful cultivation were little known in general culture.

The last year, new efforts have been made to introduce into our agriculture this oil plant. These attempts have best succeeded in Germany; and since then, the agriculturists in the east of France have, in various places, sought to introduce it as a plant more easy to cultivate than the colza, rape, or poppy.

The advantage offered by the *madia* is, that it is not difficult in the choice of soil, remains only three months in the ground, and can therefore be sown as late as 15th May—a very important particular.

The oil of this plant is rich, of good taste when fresh and cold-pressed, after a slight washing of the seed with acidulated water; when used for the manufacture of soap, it makes a solid soap; it burns well, and is as good for cooking as olive oil.

Culture.—The period most favorable for sowing the *madia* in France appears to be from the middle of April to the 20th of May; it is sown broadcast, in a well prepared mellow soil, the quantity of seed being 10 kilogrammes to a hectare.

As soon as the plant is sufficiently high to be easily distinguished, the seed is thinned out, and then, by pulling up at the first hoeing, not more than one plant is left for 28 centrimetres in all directions. After a month, it receives a second hoeing; and a third, too, if necessary.

The seed springs up in about 10 to 12 days.

The third hoeing is an expense and practice which is very useful, as it consolidates the plant and gives it a new force, and causes it to seed.

While this hoeing is going on, the plant, just before it flowers, exhales a peculiar noxious, disagreeable odor, and a viscous greasy matter exudes from it similar to chorophylle, and which sticks to the clothes of the laborers; it is removed with difficulty—ley only can make it disappear.

Some have sown it in a hot-bed, and pricked it in 33 centimetres apart. This method is longer and more troublesome, but has the advantage of a remarkable increase in the abundance of seed.

Harvesting.—The harvest takes place 90 to 100 days after it is sown; the moment is chosen when the flowers appear to be well furnished with seed, for they bear seed while not ripe, and before the flowers have disappeared. The seed should be gathered after the plantation has been examined and the flowers opened; a part of the seed not ripe grows better by drying the plant after cutting the stalk.

The plant should be cut rather than pulled up; it may be cut either with sickles or scissors, as is done in pruning trees. The stalks are placed in bundles, joining them head to head, and inclining towards the foot.

When the plant is dry, it is placed on vans, to carry it to a cart provided with a cloth. All these operations must be performed with care, for the loss of the seed lessens the profits of its cultivation.

If the plant has been well cultivated and gathered carefully, from 13 to 1,600 kilogrammes of seed are obtained from a hectare.

Birds and poultry are delighted with the seed; it is necessary, when ripe, to keep them away, for they destroy more than they consume.

When the plant is got in, it is allowed again to dry before the last seeds are ripe, that they may be more easily detached by threshing.

The odor which is exhaled, and yet more the hairs which are on the plant, prevent a careful threshing, because the operations are inconvenient; it is necessary, therefore, to watch with attention this work.

The seed is exposed in a heap in the granary, where it soon takes a deep gray color. It produces, in that state, nearly 28 kilogrammes of oil to 100 kilogrammes of seed. A hectolitre weighs from 50 to 51 kilogrammes.

The oil, when expressed cold, is from 13 to 16½ kilogrammes for 100 kilogrammes of seed, and, when expressed hot, from 11 to 12 kilogrammes for 100 kilogrammes of seed.

On the extraction of the oil.—The oil of the *madia*, very rich and tasteless at first, leaves a taste afterwards which is very disagreeable: a very simple and convenient method of taking away this taste of the oil, which is to be used for food, consists in washing in warm acidulated water the seed of *madia*.

Method of obtaining the oil of the madia sativa, without its bad taste.—To water of the temperature of 40° to 50°, (probably Reaumur,) is added a

centiéme of sulphuric acid; the grain is washed in it, then rinsed off with clear water, to take away all the acid, when it is left to dry, in order afterwards to extract the oil. Obtained in this way, the oil has no other taste, and is good for using with food, and very superior to nut, poppy, colza, &c., oil.

To give it the taste of olive oil, we have only to add 1 kilogramme of olive paste, free from water, in 50 kilogrammes of the madia oil, and filter it after a month of maceration; then it may be used for sålad, so as to deceive amateurs. This oil burns well: it lasts longer than that of colza oil, and is easily purified by washing in acidulated water.

From what has been said, it may be concluded that it is profitable to cultivate this plant, which is only three months in reaching its entire development; which, in the ground, is exposed to none of the chances of the colza, so difficult to cultivate, so fearful of the frost, and so often destroyed by the fly, which never attacks the *madia*.

If a hectare produced no more than 1,200 kilogrammes of seed, and 400 kilogrammes of oil, this plant would afford a large profit to the cultivator.

We hope that this notice will engage the attention of cultivators who have not yet attempted the culture of this plant, and induce them to make the trial.

The stalks, &c., of the madia cannot be used except for burning or to make a good manure by their decomposition. M. Bailly de Villeneuve thus estimates the expense of the culture of a hectare, [1¼ acre:]

Rent of a hectare	48	francs=	$9 60
Laborer	8	"	1 60
Three hoeings, at 24 francs=$4 80	72	"	14 40
Harvesting	10	"	2 00
Cartage	6	"	1 20
Threshing, 6 days' work, at 1 franc—50 cents, including all	9	"	1 80
Manufacture of the oil for 30 hectolitres	60	"	12 00
Seed	2	"	40
	225	"	$45 00

For which is obtained 225 litres of good oil—more than 50 gallons.

The quantity of the oil obtained, in this account, seems to us too small.

APPENDIX No. 19.

BENE PLANT.

NEW YORK, *January* 27, 1846.

DEAR SIR: Your letter of 21st came to hand on Saturday; but being much engaged, I had not leisure to give the subject-matter that attention its importance required.

The bene plant was introduced into the West India islands from Africa, and subsequently in some sections of the United States. South Carolina and Georgia, I believe, are States in which this plant has been cultivated.

The seed yields a great abundance of oil; and so great is the product, that I am unwilling to state how much oil is produced from a hundred pounds of seed, fearing the proportion would appear so large as to be almost incredible.

The plant is useful as a medicine, and I enclose a small printed sheet which I obtained from Mr. Thorburn's seed store, for your information on that head.

More than twenty years ago I purchased several casks of the oil of the bene seed, from Messrs. Suydam & Wyckoff, merchants, (then doing business in South street, New York,) made from seed sent to that house from a correspondent in Georgia, or South Carolina. The seed was sent to a linseed oil mill in this vicinity, where it was crushed and pressed. A portion of the oil was obtained by cold pressing, the residue by hot pressing. The cold-pressed oil was light colored and flavorless; the hot-pressed was a little colored, and had the peculiar smell of nut oil. I purchased this oil at a low price, for the purpose of making soap; but, finding it contained too much mucilage, I was induced to make sale of it to the house of Clark & Co., druggists, Maiden Lane, New York. The Messrs. Clark paid me two dollars per gallon for the cold-pressed, and 90 cents per gallon for the hot-pressed oil. Mr. Wyckoff used the cold-pressed oil for table oil, and found it excellent.

The plant is easily cultivated, and yields abundantly in seed, but requires a warm latitude.

I will send you, the first opportunity by private hand, some of the seed for distribution; and I will examine among my oil samples for a sample of the oil, which I will also send you, if I find, after being kept on hand more than twenty-five years, it is a good sample of the article.

Yours, with great respect,

EBEN. MERIAM.

Hon. E. BURKE.

DIRECTIONS FOR USING THE BENE PLANT—[SESAMUM ORIENTALE.]

Take eight or ten of the leaves, wash the sand off, and let them lie twenty minutes in a half-pint tumbler of cold water. A thin jelly will soon be formed, without taste or color, which children afflicted with the summer complaint will drink freely. A little sirup may be added to tempt the taste. It has been supposed that the lives of a great number of children have been saved by it, wherever it has been used. In some instances it has been administered with perfect safety to infants only a few days old.

NEW YORK FARMERS' CLUB.

DECEMBER 2, 1845.

A communication was read from Paul Duggan, esq., Professor of the Arts of Design at the Institute, now at Curaçoa, transmitting with it a parcel of bene nuts. Mr. Duggan states that the botanical name of this oil nut is guilandina moringa of Linnæus. It is of the family faguminosa. It is a native of the Indian Archipelago—is grown also in some parts of the British India peninsula; that it was introduced many years ago into Curaçoa, but only lately considered of value. The trees from which these nuts were taken are not fully grown, being only three years old. The oil of this nut is slightly colored—has little smell. It should be free from color and without smell.

The oil from the bene nut does not congeal—is excellent for the movements of the watch, and for machinery. The abraded parts of machinery moving in it are precipitated in it; and when applied to paper or other substances, this oil will so perfectly evaporate as to leave no residue. —*New York Farmer and Mechanic.*

BENE OIL.

To the Editors of the New York Farmer and Mechanic:

GENTLEMEN: The oil of bene seed is a valuable article. The seed yields very abundantly in oil, and the plant is of easy cultivation.

Some years ago, Messrs. Suydam & Wyckoff, then doing business in South street, received a large quantity of bene seed from one of their correspondents in South Carolina, or Georgia. The seed was sent to an oil mill here for pressing. The oil made from this seed was part of it produced by cold pressing, and the residue by hot pressing. The hot-pressed oil possessed the flavor of nut oil, and was slightly colored. The cold-pressed oil was colorless and without smell, sweet, and was a good table oil. The oil was unsaleable here, and I purchased the entire lot at a low price; but finding that it was not a good oil for making soap, in consequence of the mucillage it contained, I sold it to the druggists. Messrs. Clark & Co., then doing business in Maiden Lane, purchased the cold-pressed oil at two dollars per gallon, and the hot-pressed at 90 cents per gallon.

I noticed that a sample of bene oil had been presented at the last meeting of the Farmers' Club, which prompts this communication.

I have, among my oil specimens, the expressed oil of the mace, the poppy seed oil, oil of cotton seed, oil of the palm, cocoanut oil, ground nut oil, oil of the olive, and oil of the castor bean. These oils are variously affected by cold, and all of them become rancid by age and change of temperature.

The poppy seed oil is often sold for olive oil; but for many purposes it is unfit for use, in consequence of the mucillage it contains. Place this oil upon a heated iron plate, and it will, in evaporating, coat it with a varnish; it is, therefore, unfit for oiling wool.

Yours, &c.

E. MERIAM.

APPENDIX No. 20.

BROCCOLI AND CUCUMBER, &c.

CULTIVATION OF BROCCOLI.

ASTORIA, *January*, 1846.

SIR: The cultivation of this most delicious and beautiful vegetable is less known and less attended to in this country than its merits deserve. It is just as easy to grow as a cabbage, and comes into use when most of the summer vegetables have passed away.

Any soil that will grow a cabbage, or a cauliflower, will grow a broccoli. It requires, however, to be richly manured; and by far the best manure is from the cow-yard. This is equally true with respect to the cultivation of every species of cabbage and lettuce. All these plants feed grossly, and will not refuse even fresh cow manure. It is well to know this fact, because sometimes, in the absence of other manures, it may be convenient, if not absolutely necessary, for the gardener to use it; and if he had his choice, he could not select better. The red cape broccoli seems most congenial to this climate. The seed should be sown about the middle of May, in a shady border, if convenient; for the plant is naturally hardy, and thrives best in cool rather than in hot weather. So soon as the plants shoot up to the height of two or three inches, they should be planted out in rows six inches apart, and four inches in the row. This will give them ample space to grow straight, stocky, and strong. When grown to the height of seven or eight inches, they will be of suitable size and strength to transplant into the ground prepared for them, fresh manured, and fresh dug a spit and a half deep, with the manure turned in as near the bottom as convenient, to guard against the drought of August and September. The roots are sure to find their food. Give the plants a liberal space in rows three feet asunder, and three feet in the rows, for the leaf grows longer though narrower than the cabbage. The last season I planted out my broccoli upon the same ground that I used in growing cauliflowers; and, by fresh manuring and fresh digging, obtained two full crops. They will begin to fruit the beginning of October, and continue fruiting until the middle of November.

Dry as the season proved, I grew last year at Astoria, New York, the finest broccoli I ever saw. Many of the heads measured two feet seven inches in circumference, with a fine solid compact pulp. I attribute this unusual growth and healthfulness of the plants more to the character of the manure and depth of digging than to any other cause. The natural moisture of the manure was checked in its evaporation by its depth in the earth. I believe there was not a plant that did not fruit. If the main stalk, after cutting off the head and trimming the leaves, be left standing, fresh stems with small heads will shoot out round the top, very fine and tender. If the autumn proves dry, fork up the earth between the rows. It is far better and less labor than to use the water-pot. A skilful gardener will watch his opportunity, and seize a wet day for transplanting; but, if he doubts the continuance of wet weather, it is a good and always a successful plan to mix mould and manure in a bucket of water, and immerse the

roots of the plants before setting them. Follow this plan, and you will not lose a single plant, wet or dry. Your obedient servant,

JUNIUS SMITH.

Hon. E. Burke.

[Extract of a letter from James Coppuck, dated Mount Holly, N. J., Jan. 1, 1846.]

"Whilst writing, I would intrude by introducing the following to your notice. Last fall I planted a few cucumber-seeds in the following way, as directed by a friend, with no other view than the mere product of fruit:

"I dug a circular pit about 8 or 10 inches deep, $2\frac{1}{2}$ feet diameter; this I then filled to within 3 or 4 inches of its top with a mixture of one-third earth and two-thirds *hog-pen manure*, over which I placed an inch or two of earth, forming a concave hollow; around the periphery I planted a few seeds thus,  as shown by the dots around the circle. When the plants had grown to a proper size, I then placed around the bed a support of sticks diverging from the centre in a vertical direction of about 35° or 40°, thus,  so that a person might readily pass around and under the vines to collect the fruit. I observed that the vines running south produced by far the most fruit—north, but few; whilst those running east and west, each an intermediate proportion. This was steadily so from their flowering until frost.

"One bed of this size will produce from 8 to 12 and 20 cucumbers a day; and, if the fruit is not suffered to get old on the vines, it will bloom and keep vigorous the entire summer. In dry weather pour a bucket of water in the centre of the pit."

ON LETTUCE.

Hopewell, near Fredericksburg, 1846.

Dear Sir: I have enclosed you a package of lettuce-seed, which I have cultivated for several years, and have so improved the quality that last year I succeeded, notwithstanding the drought, to grow them to measure $13\frac{1}{2}$ inches in diameter, hard heads, very white, and *very* tender. I have tried a great many kinds of lettuce, but have found none to come anything near the quality of this kind. To grow them good, they must be planted on land *recently* manured with the strongest manure that can be obtained, (fresh horse-manure is the best,) well incorporated with the earth.

I have also sent you three seeds of the African pumpkin. I had a few seeds sent me last year, (spring,) but, by neglect, they were not planted until late in the season, and consequently had not time to mature its fruit. The vine grows very large—*leaves* measure 2 to $2\frac{1}{2}$ feet across; and I think this kind will prove to be a great acquisition to the pumpkin race. The seeds sent you are a part of those sent me from Africa: the seed did not mature in those I raised last year. Cultivate like the common pumpkin.

I should be glad, if you have any seed to spare, to receive such at as early a date as may be convenient. I am taking a great deal of pains to collect and prove all the fine and rare kinds, and shall next fall have a supply to send you for distribution. Truly yours,

H. R. ROBEY.

Hon. Edmund Burke.

APPENDIX No. 21.

INDIGO.

From the American Agriculturist of November, 1845.

CULTURE OF INDIGO.

It being quite out of the question to make a living in my neighborhood by cotton planting, I am turning my attention to something else. Sugar is the first article to attract attention, as it is extremely profitable; but it requires a fortune to begin with, and is out of my reach. Indigo, I have thought, might answer; but, from a small trial I have just made, it does not appear so. My little trial, it is true, is not a fair test; but, such as it is, you shall have it.

I planted, early in the spring, a piece of new ground in indigo, on which nothing had ever previously been planted; and after leaving plants enough to give me seed for another year, cut and measured a piece of the following dimensions, viz: 1,176 links of the English surveyor's chain, by 150 links, which, multiplied into each other, gives 176,400; dividing this by 100,000, the number of square links in an acre, it gives somewhat more than one acre and three quarters. From this I cut weeds to fill four troughs or vats, which, after being filled with the weed, held 120 gallons of water, which, after steeping about seven hours in the daytime, or eleven hours at night, I drew off into another vat, and beat from forty to fifty minutes, when I found that it would readily settle, and put in the lime-water (about one quart) for that purpose, keeping the froth down, of course, with oil. In this last trough or vat I had two spigot holes, one above the other, and from one I allowed the far greater part of the water to run, and then drew out the indigo and the remainder of the water in a rather coarse cotton cloth, placed in a box with holes in the bottom of it, the cloth acting as a strainer, and the holes in the bottom of the box letting the water run from the indigo. This I put in a press for twenty-four hours, in a wooden frame placed on a bench, with grooves, or rather saw-cuts, across it, to allow the remainder of the water to run out. I now took out the indigo, still wet, cut it in pieces, and dried it in the sun; out of the sun it appeared to be impossible to dry it. When the indigo was taken out of the press, each making averaged about seven pounds, or twenty-seven pounds in the whole. I have just now weighed it, when perfectly dry, and the whole weighs only three pounds. Now, at this rate indigo would be rather worse than cotton; but I have not given it a fair trial. It was planted too wide apart, and not cultivated as it ought to have been, in consequence of the cold and wet spring drawing my attention to work of more consequence. A neighbor of mine, an old Indigo planter, has just one acre of ground in indigo; he has cut his first crop from it, and assures me that he has made fifty pounds from it, and expects twenty-five pounds more from a second cutting. From the samples of indigo I have seen bought by my neighbors, most of whom spin and weave, I am quite certain that it is much adulterated with some other substance; and they assure me that it is sometimes so bad it will not dye at all. Mr. Landry, my neighbor above spoken of, has sold what little he

made at $2 25 per pound, or half a dollar per pound more than the usual retail price of the imported indigo. I send you samples of both his and mine, which I will thank you to give to some dyer, to ascertain the value of it in your market, and also a few small lumps of blue, which is three parts starch. Mr. Landry says that I do not beat my indigo long enough, and lose by it in that way, and that I sun it too much, and make it too light. He smokes his, but I cannot clearly comprehend what good that does.

It appears to me impossible to take in and secure a crop of more than one and a half acre to the hand, and this planted at three different times, that it may ripen gradually, and not all at once; and, indeed, not so much in a wet summer, of which we have too many, sometimes raining for sixty days, with no more than two or three days' intermission, which nearly destroys cotton crops, and might be even worse on indigo.

The purport of this letter is to elicit a detailed and full account, from some practical indigo planter, of the whole process of making it, as well as to ascertain the price at your market of such qualities as I send you. All the accounts that I have seen on the subject are meagre indeed; nothing at all calculated to make an indigo planter.

PHILIP WINFREE.

New River, La., *August*, 1845.

We have but recently received the samples of indigo spoken of above; and, not being acquainted with any practical cultivator of it, we handed them over to Mr. Partridge, an extensive dealer in dye-stuffs in the city for information. The following is his reply. It must be premised that he puts down the *wholesale* prices the samples might probably bring in the city; whereas Mr. Winfree speaks of *retail* prices in the interior of the country. We shall feel grateful to any of our readers who can furnish us further information on the culture of indigo in this country. We do believe it would pay the southern planter well, if he only knew the proper method of cultivating it.

Dear Sir: I have examined the samples of indigo sent you by P. Winfree, esq. The fine samples mixed with starch may be worth about 30 cents per pound for blueing clothes when washed. The squares sent loose in the box, and full of white, or rather drab colored specks, might sell at 50 cents per pound. The sample from Mr. Landry could scarcely be sold at 50 cents, but might bring more, if, on trial, it should work better than its appearance indicates. The sample of Mr. Winfree is much inferior to all the others, and I much doubt if we could persuade a regular consumer to buy it at any price, as it has evidently been injured in the making.

The best violet and blue Bengal indigo is selling at about $1 40 per pound. We are selling prime consumable quantities of Bengal at from $1 15 to $1 20. Prime Guatemala is selling at from $1 to $1 10 per pound; one pound of the latter being worth at least twice as much as any sample sent in the box, judging from appearances. There is certainly something wrong in the manipulations of all these indigo makers.

Query 1st. Do they not leave the plant to pass its period of maturity before cutting? Mr. Dalrymple informed me that it should be cut when in full flower; another East India maker, that it should be cut before the flowers come out in blossom. They all agree that if left too long, the indigo produced will be less in quality and of inferior quantity.

Query 2d. Do they not cut the plant too soon after rain? for it appears that it should have several days of dry weather before cutting.

Query 3d. Do they not ferment too much, or too little? In making indigo in the East Indies, they judge of the steeping by the color and the smell of the liquor. Sometimes it is complete in six hours, at other times it requires twenty hours. This variation in the fermentative process may often arise from the state of the weather before cutting; for, if moist from rain, the fermentation will certainly proceed more rapidly than when the weather has been previously dry for several days. It may be influenced also from the state of the plant when cut; whether it has arrived at full maturity, as described by Mr. Dalrymple, or whether cut before bursting into flower; as the latter would undoubtedly ferment more rapidly than the former, the condition of the plant being more succulent. The state of atmosphere during the process of steeping must have a decided effect in either hastening or retarding the fermentation; for when it is clear and dry, the fermentation will not be so rapid as when it is hot and moist. It is in this operation that more skill is required than in all others; and unless the operator understands this point, and attends particularly to it, no profit can be derived from the manufacture.

Some of the best indigo I ever used in England was made in South Carolina, by the late General Wade Hampton, who informed me by letter, many years since, that the art of making was lost in this country. I presume, however, that it may be recovered again by repeated experiments. In Mr. Winfree's letter he states that the seasons are often very wet, it sometimes raining for sixty days in succession, with only two or three days intermission; now such a season must be too moist for the indigofera.

With regard to the beating, it must be continued until all the green particles have become sufficiently acidized to precipitate; for whatever portion remains in a green state will be lost, this portion being soluble in water.

WILLIAM PARTRIDGE.

Mr. Allen.

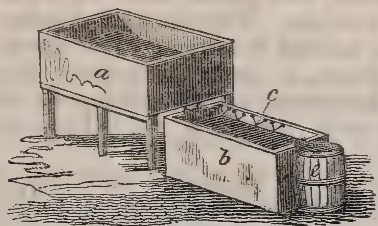
From the American Agriculturist, February, 1846.

CULTURE OF INDIGO.

I noticed some letters in your last volume upon the culture of indigo; and as it is one of the subjects to which you originally invited my attention, I will proceed to state, as shortly as may be, what I learned in my youth upon this matter. My father grew indigo, as a crop, until I was sixteen years of age, and was considered to have made a good article.

The laborers are divided into gangs of ten, and are expected to cultivate 30 acres to the gang. The soil should be moist, whether loam or clay, well drained, and divided by small trenches 24 feet apart. The indigo is drilled 14 inches between the drills. The seed is very small, and should be soaked for a night, then mixed in dry ashes or sand, and sown along the drill carefully and regularly. Four quarts of seed, carefully sown and well mixed in ashes, are enough for an acre. In this climate the seed should be sown in the first week in April. When it first comes up, it resembles white clover or lucerne, and should have the grass carefully picked by hand from the drill. When it is an inch or two high, it must be weeded

between the rows, and the soil loosened about the roots. Three weedings are enough before the first cutting, which should commence about the first week of July, or as soon as the indigo begins to throw out its bloom.



Indigo vats.

For every set of ten hands, there sould be what are called a set of works. These formerly cost about $100 or more, and were—a vat or tank, made of plank two inches thick, well joined. This vat (*a*) is 20 feet square, stands upon posts 4 feet from the ground, and is kept tight by wedges driven into the sleepers upon which the plank rests. The vat is 3 feet deep, and is called the steeper. Along side of it is another vat, (*b*) 20 feet by 10, occupying the space between the bottom of the steeper and the ground, into which the water is drawn in which the indigo is steeped when ready to be beat, or churned, as we may say. At the end of this last vat, a small tank or cask (*e*) must be placed, to furnish lime-water in the process of beating. The liquor is drawn from the steeper (*a*) by a spigot at the bottom of the vat along the beater, (*b*.) Lengthwise of this is stretched a beam, (*c*) resting on its upper ends, and revolving on journalls, and furnished with cross-arms, to the ends of which are fixed open buckets without bottoms, containing about two gallons each. Two men, standing on this beam with a handspike fixed to the long beam, alternately plunge the open buckets right and left, thus churning the liquid until it begins to show a blue fecula, which is produced by small quantities drawn from the lime cask, (*e*.)

Indigo is so easily injured by the sun after being cut, that the cutting begins and ends in the afternoon. As it is cut by the common sickle or reap-hook, it is carried either to a shed or conveyed and placed immediately in the steeper, where it is carefully spread. When the indigo is placed in the steeper from 2 to 2½ feet deep, pieces of scantling are placed across the indigo weed to keep it down, and from rising as the water is pumped upon it out of the reservoir. This operation should be accomplished about sunset; and a steeper of this size usually takes about an acre of ordinary indigo weed to fill it. The time of steeping is usually from 9 to 10 hours, depending upon the temperature of the water. The warmer it is, the sooner the process is over. But when the water assumes a light olive color, it is time to draw the water into the beater, and the process of beating commences, which is continued until the fluid becomes lighter in its general shade, and blue fecula begins to show in the water; which the sooner begins from small quantities of lime-water having been let run by a spigot, from the lime-water cask, from time to time, during the process. After the fecula shows itself distinctly in the water, the vat is left to repose for four hours, when the water is slowly drawn off by holes at different heights

so as to allow the indigo to subside to the bottom. As soon as it has done so, it is carefully collected into bags, which are hung up to drain. When sufficiently drained, it is placed in boxes two feet by one foot, to dry under gentle pressure. When sufficiently firm, it is divided into squares, by a rule and some sharp instrument, and placed under the shade to dry—commonly in the upper story of a house. The varieties of indigo were produced by the time in steeping, in beating, in liming. The shorter steeping and less beating produced the flotent, or light blue indigo. But in looking back upon this process, I am astonished at remembering the indifferent and often turbid water that was used in steeping the indigo, which must have injured its quality.

In the dyeing houses of England a filtering apparatus is made, by four boards nailed together, 20 feet long and a foot square, which is filled with coarse sand or fine gravel, with the ends stopped by two other boards with very small holes in them, and the water used is drawn through this wooden filter, from the reservoir out of doors to the vat within the house, which purifies the water. This could easily be done here. Again, the frequent rain showers that occur in our common summers must have often disturbed both the process of steeping and beating, and thus injured the indigo. From all these causes, the warm process first introduced by Dr. Anderson, of Madras, and described by him in the Annual Register of Calcutta, and given in a note appended to Bryan Edwards's History of the West Indies, must be altogether preferable. This process is under cover, and it is only steeped two hours, the water being heated to 160 degrees. A house 30 by 20 feet would contain two steepers 10 feet square, and two beaters 5 feet by 10, the heating apparatus being placed between them, and would, as I think, take off twice the quantity of indigo in a day, besides continuing the process after, by the usual one, when the nights had become too cold.

In Georgia the indigo gave two cuttings, and usually 60 pounds of indigo, in the two, to the acre, which for three acres is 180 pounds to the hand. With the warm water process, I see no reason to doubt we would have three cuttings, better quality of indigo, and probably more of it; and this Dr. Anderson stated is the case.

My indigo-house has been built now two years, and I have only been prevented by the untoward seasons of the two years past from carrying out his plan.

The following is addressed to yourself and Mr. Partridge, whose communications upon this and other subjects I greatly value. Why not throw steam into your steeper for 10 or 15 minutes, and then pump the water from your tank? What is a little curious, steam allowed to pass off at the boiling point just heats to 160 degrees, the very point which Dr. Anderson found the proper temperature for extracting, or, as I would say, taking off the coloring matter from the weed. Again, we find, in all applications of steam, it acts more promptly and more perfectly than water, as witness the Turkish bath. By this process much labor would be saved in heating the water. We would have also an exact measure of heat, and experience would soon give the due measure of time. Nothing but my age and infirmities, combined with two bad seasons, have prevented my carrying out the experiment; but I would be gratified at having Mr. Partridge's opinion upon the subject.

THOMAS SPALDING.

Sapelo Island, *Georgia.*

APPENDIX No. 22.

SPURRY.

[Extracted and translated from the Journal des Connaissances Usuelles et Pratiques for 1841, by E. Goodrich Smith, of the Patent Office.]

ON THE GIGANTIC SPURRY.—BY M. BOSSIN.

The *spergula maxima* (D. Rechenbach) is an annual, and indigenous to Courland and Livonia, and grows there spontaneously; its stalks are about 1 metre to 1 metre 40 centimetres high, while those of ordinary spurry do not exceed 60 centimetres, and those of the small from 15 to 20 centimetres. At the height of one foot it shoots forth 5, 6, and sometimes 10 stems; its growth is as rapid as that of the common spurry, and we can easily obtain two harvests in a year. Like the latter, it furnishes, when green, an excellent fodder, which is peculiarly adapted to milch kine, the milk of which it increases at the same time that it improves the quality. This fodder is equally acceptable to sheep and swine, with which it agrees excellently. When in the first harvest, it is left to seed, the seeds which disperse themselves are sufficient, after one ploughing, to procure a very good autumnal pasture, which lasts till December, or even sometimes later. It is one of the first of the green fodders which is gathered, and which is enjoyed the longest period. The culture of this plant, when not left to bear seed, improves the soil, or at least does not exhaust it. Its seed, like that of flax, must be renewed from time to time, so as not to deteriorate.

The gigantic spurry best succeeds, in my opinion, on sandy soils; but it grows vigorously on the poorest soils, as also on good ones, provided they are not too strong. I have observed that it succeeds best when sown in April, when the soil is well dried, mellow, and carefully harrowed before sowing.

It is an excellent preparatory crop for rye, as it can be cut, then ploughed and manured, in season; or, better still, sow spurry a second time, which may be cut green time enough for sowing rye by Michaelmas day. I have not manured for spurry myself, but it succeeds best when a slight manure is given to the soil. It must not be cut too soon, because the gigantic spurry grows with vigor during its flowering season. It is very useful to destroy the parasite herbs, as it grows very rapidly, and these plants do not begin to flower before the *spergula maxima* is ready to cut. For my sowing I have employed for a morgen (25 to 30 ares) from 4 to 5 kilogrammes of seed. I believe that in fertile lands 3 to 3½ kilogrammes would be sufficient.

It was in 1839 that M. Malpeyre, sen., and myself, obtained the seed. We cultivated it by comparison with the common spurry sown in July, beside it, at the same period. The gigantic spurry reached to the height of about 1 metre, while the common spurry only reached that of from 15 to 25 centimetres. Experiments were tried again in 1840. Notwithstanding the great drought, I obtained in my fields of Limones (Seine and Oise) the most satisfactory results. Sown in April, the stalks, which I presented to the

Royal Societies of Agriculture and Horticulture of Paris, and other learned societies, were from 100 to 110 centimetres long.

M. Descolombiers, president of the Agricultural Society of the Allier, and of the agricultural committee of Bourbon l'Archambault, did me the honor to write me June 28, 1840, as follows:

"I have read, monsieur, with the greatest pleasure, in the *Propagateur du Cantal*, that you have the *spergula maxima*, which I have vainly attempted to procure anew, having lost it 15 years since. If you can give me a small parcel to sow by the first rains of August, I shall hope to obtain a crop of seed in this autumn, if the frost is delayed, and I shall be most grateful for the favor.

"I ask you also to allow me to republish in the journal of the Agricultural Society of Allier the article which you have addressed to M. Richard, editor of the *Propagateur du Cantal*, on that interesting plant, which yielded 600 kilogrammes of dry straw on a little more than 6 acres—straw which my cattle ate eagerly, and equal to the best hay."

I received the following letter from the same zealous and persevering agriculturist, dated the 18th of February, 1841:

"My spurry has reached the height of 60 to 65 centimetres, and given plenty of seed, though the weather has been very unfavorable; for the ordinary spurry, sown beside it by way of comparison, has only reached to 15 or 20 centimetres. M. the Marquis of Saint Georges, my brother-in-law, who, very little favorable to spurry, showed himself distrustful, having noticed the contrast, proposes also to sow the *spergula maxima* the next spring on a great scale."

I hope, then, that new trials will serve this year to sustain our experiments; and if, as I believe, the gigantic spurry may be easily cultivated in France, it will be for agriculture a great reliance; for, what we want in autumn especially is green fodder.

BOSSIN,

Nurseryman and seedsman, No. 5, Quai aux Fleurs.

APPENDIX No. 23.

LOCUST TIMBER.

For the Prairie Farmer.

PROFITS OF GROWING LOCUST TIMBER.

MESSRS. EDITORS: Similar calculations to the following were published in the Peoria Register, some years since, for the purpose of convincing some eastern landholders in this county that an investment of that kind would not be unprofitable, even for the timber on the land in cultivation, without reference to the advantages that would result from having a large quantity of prairie land surrounding it.

Cost of 40 acres prairie		$50 00
Cost of breaking, at $1 50 per acre		60 00
Cost of 5,000 rails to fence, at $25		125 00
Cost of putting up—say at $2		10 00
Interest on 40 acres, or $50 at 6 per cent.		3 00
Interest on breaking and fencing ($195)		11 70
End of first year		259 70
Hire of hand and horse, to plough	$50 00	
Cost of locust seed, say	2 00	
Interest on $259 70	15 58	
End of second year		67 58
Hire of hand, horse, &c.	$50 00	
Interest on $327 28	19 63	
End of third year		69 63
Interest on $396 91		23 81
		420 72
The fence may now be removed, and the rails are worth say $2 per 100		100 00
		320 72
Interest on $320 72		19 24
Amount now out of pocket		339 96
Every other row one way across the field may now be taken out, which will make 1,058 trees per acre; two round rails to each tree, or 2,116 rails per acre, worth $42 32; or, for 40 acres		$1,692 80
Making 84,640 rails, at 25 cents per 100		211 60
		1,481 20

Deduct all previous expenses	$339 96
End of fifth year, a clear profit of	1,141 24
Interest on same	68 47
End of sixth year, a clear profit of	1,209 71
Interest on same	72 58
	1,282 29
Every other row should now be taken out the other way, leaving the timber 9 feet apart, giving 529 trees per acre. The lower cut will make two rails and the upper cut one, which will be in all 1,587 rails per acre. These, at $2, give $31 74; or, for 40 acres	$1,269 60
Deduct the cost of making, 31 cents per 100	129 62
	1,139 98
Add the above	1,282 29
	2,422 27

The first thinning produced 84,640 rails, sufficient to fence 16 fields of 40 acres; the second, 63,480. Added together, they produce 148,120—sufficient to fence 29 fields of that size. Your field is then set in the best kind of timber, and at the proper distance. It will admit of thinning as it grows larger; and if the distance is too great when the trees are young, they will spread without running up.

The manner of planting, you have given in previous numbers of the Farmer.

It will be seen that the above calculation includes the cost of land and every expense, with annual interest on the amount, and still shows the above enormous profit. It may be said that paper calculations are never realized. Granted. But suppose half, a fourth, an eighth, or even none of the above $2,422 27 is made; is not the man the gainer who gets 40 acres of timber for nothing? This tract, with the timber at the distance of 9 feet, would have at least ten times the quantity that would be found upon any forty-acre tract in our country, and it would be of the best quality for farming purposes. It grows rapidly wherever it is planted, and can never be eradicated from the land.

TAZEWELL COUNTY, *August*, 1845.

APPENDIX No. 24.

DAIRY.

From the New England Farmer.

BUTTER-MAKING.

Mr. Breck—*Dear Sir:* I observed an article in a late number of your valuable paper describing the system of managing milk in Devonshire, England, viz: "Whether intended for the churn or otherwise, it is scalded immediately as it is strained from the cow; after this operation it does not sour so soon, even in summer; and, if it is intended for butter-making, you have sweet milk for family use after the cream is taken off. In winter, such cream will not require more than 15 minutes churning, to bring it into butter."

I have no doubt, sir, but the above system of management will produce all the results there stated. It will also cause the cream to rise more rapidly and in greater quantity. Even warming the pans into which the milk is put will produce the latter effect, but in a less degree. But, sir, is it equally true that such a system of managing milk would produce good butter? Will it not be paler and softer, and, from the greater quantity of caseine or curd which will be produced by such a system, will it not be more liable to become rancid, if kept for a length of time, than if the milk had not been scalded?

It is certainly very important to know the different modes of managing the dairy in different countries, and in different parts of the same country; for, in my opinion, there is no art in agriculture so shrouded in darkness as that of butter-making—if the butter generally found in the markets is a proper criterion to judge by.

But there are so many circumstances which affect the quality of butter, that it would not always be advisable to adopt the exact practice of another country, or of another district of your own country, nor even that pursued on another farm in your neighborhood. In different seasons, also, the same farm will produce a different quality of butter. The constitution of the cow, the condition she is in, the kind of treatment she receives, the breed she is of, the kinds of pasture and other food she eats, the length of time she is from calving, whether she is milked twice or three times a day, and whether the hands of the milker are clean and free from all taint—all these things affect the quality of butter. The quality of butter is also affected by the state of the milk at the time the cream is taken off, i. e. whether it is sweet or sour; also by the degree of sourness of the cream or milk at the time of churning. It is also affected by the regularity of the stroke in churning; for if the stroke be quick and irregular, the butter will be paler and softer, and not so rich as if the churning had been done more slowly and regularly. Churning after the butter is separated from the milk or cream, though it may add a little to the weight, has a bad effect on the color and texture of butter.

Much also depends on the temperature of the milk or cream at the commencement and during the whole process of churning; much upon whether the buttermilk is properly expressed, and the kind and quantity

of salt used, and whether it is properly mixed with the butter—that is, thoroughly and equally. Much also depends on the degree of sweetness in which the dairy utensils are kept. I do not mean *cleanliness alone*, for they can be clean without being sweet, although they cannot be sweet without being clean. The state of the atmosphere, and the purity or impurity of the air with which the milk and cream come in contact, also affect the quality of butter. The quality is also affected by the portion of milk or cream from which it is extracted; whether from the *last* portion of milk drawn from the cow, and whether from cream that has risen in the first six, eight, or ten hours, or from that of a longer period.

The above is the substance of several of the most important circumstances that affect the quality of butter. To go into detail would extend this to too great a length. I shall therefore only further add, that all these, and some other things, have to be taken into consideration by the successful dairy woman; so that much more depends upon her ability to form a correct judgment of the method best adapted for her own dairy, than upon her adopting strictly the system of any other person or place.

Much has been said and written against touching butter with the hand while preparing it for use, as the heat of the hand injures the butter, &c. Now, sir, I do not pretend to be sage enough to enter into the philosophy of this controverted point, but I will state what I know, viz: I know that it is the general practice in Ayrshire (a county in Scotland much famed for the good quality of its butter and cheese) to clap the butter with the hand in order to express the buttermilk, and to mix the salt thoroughly through it with the hand; to take it out of the churn with the hand, and to pack it into pots or firkins with the hand. And, notwithstanding this handling, I doubt not the butter generally made in Ayrshire would find a ready sale in Boston market. I also know that the best butter I have eaten in this country was made after the Ayrshire manner, and in the months of June and July of the present year; and the whole process, from taking it out of the churn until it was packed into the pots for winter use, was done with the bare hand.

I have seen different plans of working butter besides the hand; such as wooden clappers, wooden pressers of different shapes and powers, and also cloths for absorbing the buttermilk; yet I consider the bare hand to be superior to the whole, especially if the butter is to be kept for winter use, because the use of the hand is the most certain way of getting out all of the buttermilk.

Many people, who disapprove of working butter with the hands, are in favor of washing it with water; but, in my opinion, it will be more injured by the latter than by the former treatment.

There can be no doubt but the hand is naturally warmer than either wood or cloth, and when it becomes too warm the butter will adhere to it; but there is a preventive of this warmth, viz: to plunge the hands in warm water before you begin to clap the butter, and, while the operation is going on, have some cold water at hand to dip the hands into; and if they still become too warm, then wash them again with warm water, and repeat the washing and cooling as often as required. But my remarks have extended to a greater length than I intended at the outset, and I shall now conclude by subscribing myself

Yours, very respectfully,
ALEX'R BICKETT.

LOWELL, *November* 29, 1843.

From the American Agriculturist.

MAKING BUTTER.

I am glad you express the opinion, in the leading article of your August number, that "good housewives are never tired of reading upon subjects of *this* kind," for I have just prepared a short paper on the best way of *working* butter, which, if you think proper to insert, I should not like my fair friends to think one too much.

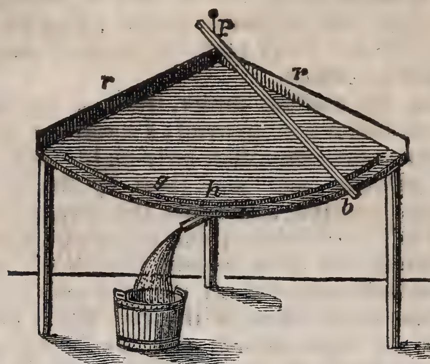
In giving directions for making butter, there is one omitted, without which all the others are literally of no avail; I mean the care of the cream. The milk should never stand more than forty-eight hours, for, if properly treated, all the oily particles will have risen by that time. When the milk is skimmed every morning and night, the cream in the crock must be thoroughly stirred with a wooden spoon before and after each addition. If this is neglected, there will be a deposite around the sides, which will contract and impart a stale taste that all the after care can never remove; and this is, I believe, the secret cause of the bad flavor of half the butter by which our markets are disgraced—fit only for the tables of those West India people, who, it is said, prefer butter that has some taste, some smell.

The directions given in the article above alluded to are, I think, very good. The London method I do not like. I would use no saltpetre; no pickle; neither annato, nor carrot juice, as color is of little importance if the flavor be good; and boiling water gives an oily taste, and so do the hands, which should never touch the butter. Working a second time, after the salt has lain in it for some hours, has a good effect, as it frees the butter from all watery particles, and gives it almost the consistence of wax. For working butter effectually, I know of nothing equal to a simple machine, which I will attempt to describe, and which any man who understands the use of tools can make in a few hours. It may not be new to you, but as I have seen no notice of or allusion to it in your former numbers, I venture to send it, accompanied by a rude drawing, to make my description more intelligible. It is much valued where it is known, for the complete manner in which it operates, and the amount of labor and time saved—a lad of twelve or fourteen years being able to work from forty to fifty pounds at once, in one-third the time required by the ordinary process. Some of the finest butter taken to the Baltimore and Philadelphia markets is made upon it.

The machine is a stout oak three-legged table, two feet eight inches high in front, by three feet behind. The top a segment of a circle of about two feet six inches diameter, with a rim *(r)* four inches high on the two straight sides; a groove *(g)* an inch or more deep, around the front, to catch the butter-milk, with a hole and spout *(h)* in the groove, to carry it into a pail beneath; a heavy bar *(b)* two inches thick, moving freely on a pivot *(p)* both horizontally and vertically.

The butter must be spread upon the table, and pressed firmly with the bar, moving from side to side, and back again; then turned with the paddle, and the pressure repeated until all the butter-milk and water have run off, after which it can be printed for market, or packed in kegs for exportation. If it is to be sent to a hot climate, it ought to be closely packed in stone jars, of not more than twelve pounds each, covered with a linen rag, upon which put a layer of salt, at the least an inch thick; cork the jars, cover closely with coarse cotton or linen cloth, and pack the jars

in kegs, an inch or more larger every way than the jars, with pulverized charcoal rammed between and over the top. I have known this done, and when unpacked in Liberia the butter was perfectly good, and hard enough to be spread with a knife—at least so said those who ate of it.



A butter-worker.

No dairy-maid in our part of the country need be told that this table must never be used for any other than the specified purpose. She would be almost as much affronted as if you told her to *wash* her milk-pail or *strain* the milk. This reminds me of Miss Edgeworth's account of the Irish method of making butter, which I will condense for the amusement of those little girls who have not had the good fortune to read her delightful story of Harry and Lucy.

She tells of a visit the children made to a dairy, where the maid put three gallons of cream into a churn, and, after churning for three quarters of an hour, produced *nearly* three pounds of butter. This was pressed to get the milk out, and then often washed in fresh waters, after which it was laid upon a flat dish, and cut into small pieces with a wooden slice, in order to have the cow's hairs picked out, which had fallen into the milk. Many of these hairs stuck to the edge of the slice, and the rest she picked out with her fingers! * * * * * * *

This "picking out" is an improvement upon the method said to be practised in one of the western States, from whence the story is told of a traveller who requested his hostess to send the butter and the hairs to his table upon separate plates, as he preferred mixing them for himself.

THE DAIRY.—BUTTER MAKING.

Smithfield, R. I., *December* 23, 1845.

I enclose an extract from a report on butter, made to the Rhode Island Society for the Encouragement of Domestic Industry. If you think it worth inserting in your valuable paper, let it appear as early as possible.

The rock-salt must go up this winter, to avoid the heavy canal tolls; and the small white-oak kegs must be contracted for soon. Half the winter's butter used in Rhode Island comes from the State of New York; and its price is diminished from four to six cents a pound by the use of Salina salt. This is a heavy tax on the farmer.

Butter made agreeably to the following directions sells in the Providence market readily, in large 100 lb. kegs, at 25 cents per lb. If in the small kegs of from 25 to 50 lbs., it brings from 25 to 27 cents. The same butter salted with New York salt would only be worth from 19 to 22 cents per lb.; and by the first of April it would be bitter and rancid. Your salt is not preservative: it will not answer for beef, pork, or fish. Why should it be used for so delicate an article as butter? Its bitter taste, and its easy solution in damp air, are no objections to its use for cheese.

STEPHEN H. SMITH.

Luther Tucker, Esq.

BUTTER MAKING.

Milk apartments, &c.—The milk-cellar should be deep, well ventilated, and dry; the bottom covered with stone flagging. Well rammed clay is preferable to bricks, as they will absorb milk and other liquids that may fall upon them; they cannot be cleansed, and will soon contract mildew—the smell of which, like the odor of cheese, vegetables, fish, or foul air of any kind, will be imparted to the cream and butter. Over this cellar should stand the dairy-room, with shelves to set milk upon in *cool* weather; the cellar to be used during the extremes of heat and cold. The temperature of the milk apartment, if possible, should never be above 65 degrees, nor below 45 degrees. Set-kettles should not stand in the dairy-room; neither should churning, cheese-making, or cleansing milk vessels be done there, but in a convenient room near by.

Cream may be kept good much longer if it be kept in a white-oak vessel, with a tight cover, and a faucet or tap near the bottom to draw off the milk when it settles, before the customary daily stirring. The quality of the butter is much improved by this management. If the milk be not drawn off, and it be churned with the cream, the butter will be longer in coming, and it will show specks of sour curd, taste like cheese, and will soon become rancid. Butter will come quickly at all seasons of the year, if the cream be of a temperature of from 60 to 75 degrees; to this end, use hot water in winter and ice in summer, but never add either to the cream in or out of the churn.

Salt.—Pure salt crystallizes into perfect cubes. All other forms of crystallization found in common salt arise from impurities; those of a needle shape in Liverpool bag, or blown salt, indicate the presence of lime, magnesia, &c. Epsom and Glauber's salts are frequently found in small quantities; in the process of making salt they crystallize last. When water is added, or on exposure to damp air, they dissolve first; hence washing salt purifies it. One great cause of the failure in making good butter may be traced to the use of impure salt.

Rock salt and the large lumps of Turk's Island salt, washed, dried, and finely pulverized, are preferable to all other kinds, being highly preservative, and hardening the butter, so that it will be sooner ready to work over

in warm weather. The Liverpool bag or blown salt, the Salina salt in small bags, from New York, and the fine part of every kind of imported salt, contain a great portion of impurity: they are not preservative, do not harden the butter, and give it a bitter taste.

Less than one ounce of pure salt is sufficient for a pound of butter—many put in half an ounce. In all cases leave out sugar and saltpetre.

In the manufacture of cheese, a preference is sometimes given to Liverpool bag or blown salt. This salt contains salts of lime and magnesia, which attract moisture from the air, and have the desirable effect of softening the cheese; and the pungent, bitter taste which they impart to it, is an improvement in the estimation of some.

General remarks.—The cream should not rise more than 36 hours: it should be sweet when taken off, and sweet when churned; yet there is a degree of maturity to be acquired by keeping. The kegs for packing butter should be made of white-oak, bilging in the form of casks, for the more perfect exclusion of air and convenience of transportation. If the butter is not to be sent to a warm climate, or a foreign market, let the *bilging* kegs have moveable covers, to accommodate inspection; they should be soaked in a strong brine, made also of *pure salt*, in order that justice may be done to the purchaser in tare, and to save the butter from being spoiled to the depth of one or two inches all round, from its contact with dry wood. In case the wood is any thing but white-oak, there is danger of its giving an unpleasant taste to the whole. For the convenience of families, the size should vary from 25 to 50 pounds. A large keg of butter is exposed to the air for a long time while on broach in a small family; the bottom, in consequence, becomes rancid.

The consumer will cheerfully pay an extra price for 100 pounds of butter packed in four kegs instead of one. No salt should be put on the sides, bottom, or between the layers. If the kegs are made with covers, put a cloth over the top, and cover that with pure fine salt. Keep a cloth wet with strong brine over the butter while the keg is filling, to exclude the air. The practice of washing butter is not approved of in Europe; it destroys its fragrance and sweetness by dissolving the sugar of milk, which, it is said, is always present in good butter. It is practised in Holland when the article is designed for exportation to India; then the operation is performed with cold, strong, limpid brine, made of pure salt and pure water. Water that has lime in it will not answer, as the lime is readily absorbed by the butter.

To exclude the air more effectually during the process of putting down, let a little melted sweet butter be run into the cavity where the bottom head and staves come together; then, after each layer is completed, let the dairy-woman pass her finger round so as to press the butter hard and close against the side.

From the Albany Cultivator.

CONNECTICUT CHEESE DAIRIES.

In our late excursion through Connecticut, we were glad to find satisfactory evidence that the character of that State for the manufacture of good cheese is still maintained. The two principal cheese neighborhoods which we visited were Goshen and Winchester. The first of these towns

became famous for its cheese at an earlier period than any other section of the country; but, though the place still holds a prominent rank in this respect, we are inclined to think, from what we saw and heard, that, for *general* reputation, "the sceptre has departed from" Goshen, and is now held by Winchester.

From Mr. A. Miles, of Goshen, a large dealer in cheese, we obtained some facts in regard to the quantity annually made there. The average quantity exported from the town is about 500,000 pounds. The quantity of butter sold is small, being only about 40,000 lbs. per year. Cheese has fallen much in price within a few years, owing to the increased quantity thrown into market. It sells this season, while new, at five cents per pound at home, or within the town. The average quantity made per cow is not known, but may be estimated at 300 to 350 pounds. Some good dairies make much more. Mr. Lawton sold last year an average of 403 pounds per cow; and, with what he kept for his own use, probably made 425 pounds per cow.

Mr. Lewis M. Norton, of Goshen, was the first manufacturer of what is called *pine-apple* cheese, in America. He commenced making this article in 1808. He had at that time no knowledge of the mode in which it received its peculiar form and qualities. He saw some which came from England, and set himself to work to imitate it. His first trial succeeded so well that he was encouraged to persevere, and he has so perfected the whole process, from the "running up" of the curd to the sale of the cheese, as to entirely distance all competiton.

Mr. Norton is this year using the curd from ninety cows for making pine-apple cheese. The principal portion of this curd is bought of his neighbors, for which he pays them the same price per pound that common new-milch cheese brings, which is five cents this season; so that those who sell him their curd save all the labor of pressing and curing their cheese, besides gaining considerable from the greater weight of the curd.

The curd is kept for twenty-four hours before it is made into cheese. The advantage of this is supposed by Mr. Norton to be, that a degree of fermentation takes place, which being checked at a critical time, by the cutting of the curd, preparatory to its being formed into cheese, is not renewed after it comes from the press; thus preventing the defect of the cheese being hoven or blown.

The curd is rapidly cut into pieces of not more than a fourth of an inch square, with a machine invented by Albert Loomis, Torringford, Connecticut, which Mr. N. prefers to any curd-cutter he has seen. After being cut, the curd is put in a cheese cloth, placed in warm water, and the temperature gradually raised by pouring in water that is still warmer, till it reaches 105 degrees by the thermometer. This does not *scald* the curd, which, according to the practice of the best cheese-makers in England and in this country, is, we think, discountenanced. The curd is next cooled, by adding cold water, to the temperature of 88 degrees, when the whole of the water is drawn from the vat, and the curd weighed, and salted with the finest kind of table salt, (four ounces of salt to ten pounds of curd;) and, after being well stirred, is put in the press, where it remains twenty-four hours, or a longer time, as is convenient, as it takes no hurt by remaining forty-eight hours. The curd is weighed immediately over the tub, being drawn up by a pully; and when this is done, is again lowered into the tub, where it is salted.

The cheeses are pressed in moulds, made of sound blocks of oak timber,

about twenty inches long and ten inches square. They are sawed lengthwise through the middle, and each half is carved or worked so as to give the general shape of a pine-apple—one half in each part. From the cavity to the upper end of the block, a groove is cut in each part, which, when the parts are placed together, makes a round channel of about two and a half inches in diameter, for passing the curd into the mould. When the two parts of the block are put together, in such a manner that the cavities match each other, and are strongly keyed into a frame, they form the mould for pressing the curd. The pressure is applied by means of a screw, operating on an upright, round piece of wood, which fits the channel in the block, and, as it is forced down, compresses the curd in the mould. The presses are very compact and strong, and appear to answer the purpose well. He had sixty-eight of them, and makes twenty-eight cheeses per day, weighing, when dried, five pounds each. When the cheeses are taken from the press, they are trimmed, then placed in nets and hung in water of the temperature of 130 degrees. This is to soften the outside, that it may receive the desired impression from the net, which is done by taking them from the water while enveloped in the nets, placing them in a frame and straining the nets tightly over them by means of screws. This indents the threads of the net into the cheese in such a manner as to give them the external appearance of the fruit from which they are named. After this operation the cheeses are hung up in the nets from three to five weeks, for the outside to harden, and are then set on shelves having suitable hollows or concavities for the cheeses to rest on. In the centre of each concavity a hole two inches in diameter is cut through the shelf, the more freely to admit the air, and allow any liquid that may come from it to run off. The nets used for the cheese are made of three-threaded flax-twine, and the manufacture of them costs, exclusive of the material, about five cents each. They will last three or four years.

Mr. Norton sells his cheese in New York, Baltimore, and other southern cities. It usually nets him about ten cents per pound, after deducting commissions. How much greater are the actual profits derived from this kind of cheese than are obtained from other kinds, we cannot tell. Mr. Norton has evidently incurred great expense in his fixtures, and in the time and study he has spent in bringing the manufacture of the article to such complete perfection ; and this ought, in justice, to secure him some corresponding advantages. He, however, makes no secret of any discoveries or improvements which his protracted and indefatigable labors have effected; but, with a highly commendable liberality, freely permits the most minute examination of his systematic operations.

CHESHIRE CHEESE.

The last Journal of the English Agricultural Society contains a prize essay, by Mr. White, of Warrington, on making cheese in Cheshire. As we have not room in our pages for the whole article, we condense and extract from it.

Time when cheese was first made in Cheshire.—The fame of the cheeses of Cheshire is of very ancient date—at least as old as the reign of Henry I, (A. D. 1100.) The Countess Constance, of Chester, though the

wife of Hugh Lupus, the king's first cousin, kept a herd of kine, and made good cheeses, three of which she presented to the Archbishop of Canterbury. Giraldus Cambrensis bears honorable testimony to the excellence of the Cheshire cheeses of the day.

Quantity made in the county.—There cannot be less, upon a moderate calculation, than 12,000 tons made in that county annually; a considerable portion of which is of excellent quality.

Art of cheese-making.—The art of cheese-making consists in the complete extraction of the whey, and in the proper compacting and curing of the curd. The richness of the cheese depends upon the quality of the milk, or, in other words, on the proportion of cream which the milk contains. The cheese of Cheshire is professedly made from new milk, or milk from which no cream has been taken. It is, however, well known that in many dairies, in the morning, before cheese-making, a small quantity of cream is skimmed off the previous evening's milk; this cream is either churned by itself, or mixed with whey-cream, by which there is obtained a better quality and greater quantity of (so called) whey-butter. It may appear singular to some that any portion of cream should be found in whey; but such is the fact, and the means used in Cheshire for extracting it are very simple.

Making of butter from whey-cream.—This varies very little from the process of making butter from the cream of milk. The cream is kept for three or four days, or until it has become clotted, (provincially termed *calved.*) Those who make the best whey-butter have a spigot and faucet to each of their cream mugs to let off the whey, which in the course of a few hours settles at the bottom, and which, if allowed to remain, imparts a rank flavor to the cream, and consequently to the butter. The temperature of the cream, when put into the churn, is generally ascertained by the hand; but if a thermometer be used, the heat which I would recommend is 60°, having found that the best. If it be much *higher* than this, the butter may be expected not only to be soft, but inferior both in quantity and quality; and if much *lower*, the operation of churning will be prolonged, and indeed tedious. At this heat the time in churning will probably be about an hour and a half. It will perhaps be necessary in cold weather to put hot water into the churn, and in warm weather to put in cold water, in order to attain this desirable object as to heat. From 100 gallons of milk there will not be less than 90 gallons of whey, which should yield from 10 to 12 gallons of cream, or $3\frac{1}{2}$ to 4 pounds of butter. The quantity of whey-butter per cow is about half a pound per week, taking the season through; but with that small portion of cream of the evening's milk added, the farmer often churns as much as three quarters of a pound of butter per cow per week, or from 20 to 25 pounds per annum. One pound of salt is sufficient for curing 37 pounds of butter, if for present use.

Number of cows kept, and produce.—The number of cows kept for the purpose of a cheese dairy is seldom less than 8 or 10, or more than 70 or 80, and is of course regulated by the size of the farm: these average about 90 or 100 statute acres, upon each of which about 15 or 18 cows are kept. From 18 cows, a cheese of from 36 pounds to 54 pounds weight is made daily during four or five months of the summer. The annual produce of cheese per cow depends both upon the quality of the animal (with the mode of keeping her) and of the *land*, or rather the *herbage.* I have known many farmers sustain great loss by not feeding their cattle

sufficiently well in winter. With judicious management, about 3 cwt. of cheese (of 112 pounds) may be considered as the average amount made per annum upon land let for 30*s.* a statute acre; but in a few instances 5 cwt. per cow, and even more, is sometimes made. This can only be from a small and choice stock.

Milking.—This operation commences about five o'clock in the morning, and five or six in the evening. In this county it is the practice for most of the servants, both men and maids, to assist, and for the cows to be milked in the cowhouses (called here "skippons") all the year round. When, as is usual, there is one milker for six or seven cows, the milking seldom exceeds an hour and a quarter. The milk of new-calved cows is not mixed with the other until about four or five days after calving.

Offices and utensils.—As the evening's milk is seldom made into cheese until the following morning, and sometimes in small dairies (where four "meals" are used) not until the second morning, a cool "milk-house" is necessary; on which account it usually occupies that side of the farm-house least exposed to the sun. The utensils in which the milk is kept are usually portable shallow earthenware vessels, called "pan-mugs," and in some dairies leaden or zinc coolers. Most of the milk-rooms have lattice or wire windows for the circulation of air, and the floors are laid in a sloping form for the free escape of the cold water with which they are daily swilled throughout the summer months. If precautions of this nature be not attended to, there is a risk of the evening's milk becoming *sour;* in which case, whatever quantity of new milk be added to it in the morning, the cheese will be *sour* also. I am led to believe that a temperature of as near 50° Fahrenheit as could be maintained, would be the best for a milk-house throughout the year. The *dairy* is generally situate near the milk-house, and fitted up with two *set-pans* or *boilers*—a large one for scalding the whey, and a smaller one for heating water. The "cheese-presses" and "screw" are kept within this room, and the operation of cheese-making is here carried on.

Lever pressing.—Poles, weights, and screws are now superseded by a new lever press. The advantages of this over the screw are, *that it sinks, by its own action, with the curd—any degree of pressure required can be applied and gradually increased, and less attention is necessary;* whereas the pressure from the screw is sudden and uncertain, and, having no self-action, requires the dairy-maid's assistance every five or ten minutes to render it effectual.

Quantity of salt required, and temperature of the milk.—A farmer in South Cheshire, well known for his introduction of improvements in agriculture, has commenced the system of weighing his curd previous to salting it, and he says he uses salt in the proportion of 1 pound to 42 pounds of curd. He also informs me he sets his milk together by a thermometer, and at a temperature of 76° or 77°.

Quantity of cheese milk will give.—It has generally been considered that a gallon of milk (supposing little or no cream has been taken from it) will produce, upon an average of the season, 1 pound of saleable cheese; that is, when the cheese is four or five months old. In autumn there is always more curd from the same quantity of milk than at any other part of the season.

The curd-mill.—This is of recent introduction, and it is only in a few dairies that it is met with; some dairy-maids highly approving, others ob-

jecting to it. I think it will soon be more generally adopted, as it effects a saving in time, and breaks the curd more regularly than it can be done by hand.

A recipe for curing the maw-skins (*stomach*).—Procure the skins from the butcher the year previous to their being wanted; clean out the chylous matter, and every other apparent impurity; the inside is then turned outward on a table, and salted; the skins are then laid one upon another, with a layer of salt between each, in a deep earthenware vessel similar to a cream mug; they are then covered over with salt, and have a lid of slate or flag placed on the top. They are taken out as wanted, about a month previous to being used, and the brine drained from them. They are then spread on a table, and fine salt is powdered on each side. In this state they are rolled with a paste roller, distended with a splint of wood, and hung up to dry.

Mode of making rennet from maw-skins.—The *rennet*, or *steep*, as it is commonly called, is next added. I have already stated, in the introduction, that this is an infusion made from the preserved stomach or maw of sucking calves, thence called *maw-skins*, or *bag-skins*. To define the quantity of rennet sufficient for coagulating a given quantity of milk is a very difficult matter, as the maw-skins vary so much in quality. When the farmer is laying in a stock for the year, he generally calculates upon a dozen of skins to a ton of cheese, but the skins vary in size; (the price when cured is from 6*s*. to 9*s*. per dozen). In using them, it is the practice often to cut two skins at once. Three square inches taken from the *bottom* (or strongest part) of one, and one or two inches from the top (or weakest part) of the other, is generally found sufficient for sixty gallons of milk. These two pieces of skin are put into a cup containing about half a pint of lukewarm water, with the addition of a tea-spoonful of salt, some part of the day previous to being used. The water thus impregnated with the maw-skin is passed through a sieve into the milk; but the skin itself is generally, though not always, kept out. The rennet cup is well *scalded* before being used again. I have been told that some farmers make a sufficiently large quantity of rennet to last for several weeks, and find it to answer better than making a small quantity daily. The question is, will it keep *sweet?*

From the Albany Cultivator.

MANUFACTURE OF CHEESE.

The following is an extract from the statement of Alonzo L. Fish, of Herkimer county, who received the first premium of the New York State Agricultural Society for the best cheese dairy, in 1844.

Calves' rennets *only* are used, after being dried one year. There are less animal properties in them than in new rennets, and will not make cheese swell in warm weather; and, on shrinking, leave them (like honey comb) full of holes, with a rank flavor.

Calves whose rennets are designed for cheese-making are not allowed to suck sick cows, or those giving bad milk, but are fed a plenty of good milk from five to ten days old; twelve or fifteen hours after sucking, when the gastric juices are most abundant and pure, the rennet is taken

out and stretched on a bow; as much fine salt is added as will adhere without draining, and hung in good air to dry. Milking is done in tin pails, and strained through a large tin strainer into a tin vat, where it is not skimmed nor moved till the cheese is made. The pails are set into a common sap bucket, which being light, and smaller at bottom than top, a little press on the pail will fasten the bucket to it so that it carries with the pail without any inconvenience. A light tap on the bucket will drop it, and leave the pail clean and not bruised. A tin vat, large enough to hold the milk, is set within a *larger wooden vat*, with one inch space between the sides and bottoms of the two to admit water, which is cooled by ice and heated by steam; which water cools the milk, to take out the animal heat, warms it to receive rennet, remains and heats whey, and scalds curd. It is discharged by a cock, to pass off into a tub, and scalds bran or meal for slop feed when it is required. Scalded feed is required daily when the cows are milked on hay feed. A large reservoir is built of stone and cement, to contain fifty hogshead of rain-water from buildings, to discharge by a cock into the above described space, into a steam generator, or into a tub, or any other place in the lower rooms where it is desired. A pump affords water to this apparatus in case of drought. Thus the same water is made to perform three distinct offices, by no more labor than to turn three cocks with the thumb and finger.

After the water in the reservoir is not wanted for cheese-making, a pipe conducts it into the top of ice-house, to freeze in solid mass in winter, for cooling milk the next season. No skimmer, pail, or dipper is required about this apparatus, only to milk in, as the cream which rises over night is not separated, nor no dipping of milk, whey, or water. The heating is done daily by a handful of chips or four quarts of charcoal, and all shift of apparatus can be made with one hand, while the other is employed in the milk or curd. A young man is hired at $11 per month, for eight months, to take the whole charge of nursing, feeding, making, and taking care of milk and cheese through the summer, and does no other business. He is required to keep a register, daily, of the variation (if any) of heat, salt, quality and effect of rennet, number of cows milked, quantity of milk from which cheese is made, condition of curd when put to press; when cheese is put on shelf, that it is weighed and numbered upon the bandage, so that, when cured, the result of certain variations may be known. An inch-pipe passes from the steam generator, and discharges steam into water under the tin vat; in ten minutes the whole mass is warmed to ninety degrees, to receive rennet. The cheese is then turned off (which would otherwise be lost) into a tub, which stands high enough to discharge into the cheese vat and scald it after the cheese is made. Hot water is drawn at any time from the same to cleanse pails, cloth hoops, &c. Calves' rennets only are used, after being one year dry, they being less apt to make cheese swell in warm weather, and of better flavor. A piece of rennet, to bring curd in forty minutes, is pounded fine in an iron mortar, and soaked a short time in warm water, mixed with a little annatto, drained, strained, and put into the milk. When come, the curd is cut in large pieces with a wood knife, thickest in the middle, to give it a slight pressure before there is much surface exposed to be rinsed by whey; after standing ten minutes, the pieces are cut smaller with the same knife, then broken up by putting the hands to the bottom of the tub, bringing them through to the top, with fingers spread, with a slow motion, to give it all a slight pressure without tearing fine, while tender.

Heat is kept as high as eighty-eight degrees while working, steam let on; the motion and pressure with hands increased with increase of heat and toughness of curd; heat is kept up to continue the action of the rennet, as it is most active when warm; heat raised to ninety-eight degrees; the steam is then turned off; it is kept at that heat thirty minutes. The heating is now done; the water and whey are discharged. One pound of fine salt to fifty of curd is added, while warm, to shrink the curd and prevent holes in the cheese. After getting cool, it is put to press; the pressure is from five to seven tons. In six hours it is turned into clean cloth; and again, in twelve hours more, is taken out of the press and put upon the shelf, weighed, bandaged, greased with oil or whey butter—turned daily. No greater heat is ever used in the operation than the natural heat of milk, (ninety-eight degrees.)

From the Albany Cultivator.

PRODUCTS OF THE DAIRY.

We intimated, in closing our remarks upon this subject last month, that we should make some suggestions as to "the means which should be adopted to secure the greatest increase in quantity and improvement in quality of dairy products." Before attempting this, however, let us first see what is the quantity now actually made in most of our dairies. Upon this point we have very little positive information, and must rely mainly on the opinions of dealers and persons who are well acquainted with the dairy business. Our intercourse with farmers and dairymen has enabled us to judge perhaps with some degree of correctness, especially as we have hundreds of times asked the question, "How much butter or cheese do your cows average in the season?" To this question we have received various answers; some putting the amount as high as 200 pounds, others at 150 pounds, and many nearly or quite as low as 100 pounds, of butter. We suppose that two and a half pounds of cheese are about equivalent to one of butter, so that the range in the average of cheese dairies would be from 250 to 500 pounds. Our own conviction, strengthened by the opinion of a number of dealers in dairy products with whom we have consulted, is, that the average production of butter cannot exceed 125 pounds per cow. The average product of cheese cannot much exceed 300 pounds. It is not asserted that these are the actual average products, but the amount here assumed will be found, on a careful inquiry, very nearly correct. The extremes, as before stated, are far above and below this amount.

For the purpose of showing what may be done with good cows and good management, we now propose to give a few statements which have come under our notice, or been communicated to us by persons engaged in this business, and, to give our readers an opportunity of judging correctly in the premises, we shall accompany the statements, as far as practicable, with an account of the measures pursued to arrive at the results spoken of.

We will first give some extracts from the report of the committee on cheese dairies to the New York State Agricultural Society, February 13th, 1845. From that report we learn that Mr. Abraham Hall, of Floyd, Oneida county, has made the past season, from forty cows, 23,427 pounds of cheese, and 200 pounds of butter. This is an average of five hundred and eighty-

five and five-eighths pounds of cheese per cow; and if we add the butter, we have equivalent to 598 pounds of cheese per cow. To accomplish this, Mr. H. informs us that he has 100 acres of pasture, (in addition to the cows, four horses and three dry cows are kept,) of good quality, though not very abundant, and about fifty-two acres of meadow. Cows are supposed to consume about two and one-fourth tons of hay each, as they are fed in stormy weather in summer, as well as a full supply in winter. Has not fed sixty bushels of grain to cows. The whey was all fed to twenty of the oldest cows, and Mr. Hall has no doubt that the twenty cows to which the whey was fed have made full 700 pounds each. Cows come in from the first of April to the first of May. They have access to salt at all times, which is considered important. The cows are well selected, regularly milked, and attended to in every respect. The cheese is made with great care and attention, and brings the highest price in market, having been sent to Philadelphia for several years past; but the last year a considerable portion of it was shipped to England. There will hardly be spare room in this article to give the details of the process of manufacture. We hope to hear more from this dairy next year.

From the same report to the State Society, we learn that Mr. Alonzo L. Fish, of Litchfield, Herkimer county, has made during the last season, previous to the 17th of September, an average of 592 pounds per cow; and Mr. F. estimates the quantity for the season at 700 pounds. The average the last three years, from twenty-five cows, has been 590 pounds. Mr. Fish also feeds the whey to his cows, and about the first of August commences feeding cornstalks (raised broadcast) once a day, to keep up a full flow of milk. While giving milk in winter, the cows are fed four quarts of shorts, or one peck of roots, per day. The dairy furniture and fixtures, buildings, &c., are convenient, and all well attended to. Here is an annual product of $41 40 from each cow for three years in succession—a handsome product truly in these times of low prices. Mr. Fish received the first premium from the State society for the best managed cheese dairy.

Mr. Elisha Baker, of Bridgewater, Oneida county, made in 1843, between April 15th and December 1st, 10,000 pounds of cheese and 1,000 pounds of butter, making an average of 500 pounds of cheese and 50 pounds of butter from each cow. In addition to hay and grass, the cows were fed two quarts of oatmeal per day, mixed with the whey from the dairy. The cheese was sold at five cents, and the butter at fourteen cents; making thirty-two dollars per cow.

We have thus glanced at some of the *large stories* from cheese makers, which are sometimes doubted, and often pronounced false by those who have no idea that any one else can make more than they have done, and are unwilling themselves to make even an effort to go beyond the old mark. These cases might be multiplied to almost any extent, had we room. Suffice it, however, to say, that there cannot be the slightest doubt of the correctness of the foregoing statements, and that the amount stated was actually made.

Let us now glance for a moment at the causes which have produced these results—results so different from those in common dairies. In the first place, we find a good selection of cows, every one of which is capable of making as much as the best in many of our dairies. Where is the dairyman who has not in his yard cows which will make nearly twice as much as others kept in the same manner, and treated in precisely the same way

in all respects? This has been our experience, and we have no doubt that it is so almost everywhere. Now, if we select, for our full number, cows of this character, the product will be at once greatly increased, without any additional allowance of feed. But where are these cows to be had? All farmers cannot have the best, it is true, but nearly all may have better animals than they do, by proper selection, if purchased, or by more care in breeding if raised by themselves. The truth is, very little attention has been given to the breeding of dairy cows, and too many dairymen depend on keeping their number good by purchases from *droves*, which are picked up in sections where little attention is given to dairying, and driven into the dairy districts to sell. Many of these are good animals, and many of our dairymen are good judges of cows, but we often hear them complain of the difficulty of purchasing good cows. We must raise more heifers expressly for the dairy, with direct reference to their milking qualities. But we have been led from the legitimate train of our remarks, to glance at the subject of breeding dairy stock, which we have not time to pursue.

Cows, to produce large quantities of milk, must have warm, well ventilated stables, and a full supply of suitable food. So important is the first point considered, that very few farmers now allow their cows to remain in the yard in cold weather; and when they are secured in good stables at the first approach of uncomfortable weather, and kept warm and well fed until they get a full bite of grass in spring, they will hardly fail to remunerate their owners for the extra expense. There can, however, be no extra expense in point of fact, for cattle kept warm will consume far less than when exposed to the inclemencies of the weather in this severe climate. In the cases of Mr. Hall and Mr. Fish, above referred to, very little grain or roots was fed, the principal addition to the usual food being the whey, instead of feeding it to hogs, as is usually practised. These gentlemen, with many others with whom we have conversed, are of opinion that as many pounds of cheese may be made from feeding the whey, as of pork, while the value of the former is usually greater than that of the latter. Mr. Baker fed about two cents' worth of oatmeal, besides the whey. For this he doubtless was well paid.

The greatest secret, however, in managing cows, consists not so much in the amount of food given, as in the regularity with which it is given, and the care and attention bestowed upon them at all seasons of the year. They should of course be fed liberally in winter, and more especially in the fall and spring, and have during summer an abundance of suitable pasture, and plenty of pure water and salt. They should be milked regularly and quickly, by the same person, every day, if possible, and treated with *gentleness* and *civility*, (an important feature in dairy management, which many persons have not yet learned,) so as not to worry and disturb them, either in driving or in milking.

We have given the product of several cheese dairies in which a little extra feed was allowed, and for the purpose of showing that large products may be obtained without extra feed. We now propose to give the product of a few butter dairies within our acquaintance, assuring our readers that we are acquainted with the individuals, on whose statements we depend, and that there cannot be the slightest doubt about their correctness. We do not intend here to give extravagant accounts, but such as will show what may be done by good care and moderate feed.

Mr. Porter, of Western, Oneida county, has a dairy of twelve cows and

three heifers—one of them three years old, and two of them two years old. From this dairy he has made, the last season, 2,600 pounds of butter for market, besides supplying a family of seven to nine persons during the year. This, it will be seen, is 173⅓ pounds; and if we add the amount consumed in the family, the quantity can fall very little if any short of 200 pounds. Mr. P. says: "We winter our cows on hay principally. After they come in, in spring, we allow them three quarts of oatmeal each per day, until they are turned out to grass. In my opinion the whole secret about making a large quantity of butter is, to keep the cows well through the winter; keep them in warm stables, and feed a little grain in spring. They must of course have an abundant supply of pasture, and an eye must be had to the management of the milk and butter." This may be set down as a good yield.

Mr. Timothy Wilcox, of New Hartford, informed us, early in November last, that he had made, up to that time, from five cows, 1,135 pounds of butter. Mr. Wilcox expected to make up the amount to 1,200 pounds before the close of the season. Besides this, milk was used in the family when wanted. One of these cows was two years old, one three years old, another four, and the others older. *Nothing but hay and grass was fed during the year.* One remark made by Mr. W. struck us as important. It was this: "I have milked these cows every time myself." Here, in our judgment, lies a part of the secret. (We hope that when Mr. W. sees this, he will go at once to the post office and subscribe for an agricultural paper.)

Mr. Brainerd, of Western, has made from sixteen cows, previous to the 15th of November, 2,720 pounds for market, besides supplying a considerable family. Here we have 175 pounds from each cow. This dairy was also kept on hay and grass alone, (except about 150 pumpkins in the fall,) but they were well fed and well attended to.

It is unnecessary to multiply instances; but we will say, in addition, that our friend Lewis Eames, of Lee, has uniformly made from 160 to 180 pounds for market annually. The dealers in butter all agree that where such large quantities are made, the quality is uniformly good; better than when small quantities are made. Good attention to one branch secures, in a great degree, success in the other.

The remarks made in regard to selection of cows, and their management for cheese dairies, apply equally well here; and we can only say that to equal, and even excel, the individuals we have named, farmers have only to procure good cows, give them good feed, both summer and winter, see that they are at all times protected from cold and stormy weather, have plenty of pure water and free access to salt, are regularly milked by careful hands, and, finally, that the milk and the cheese or butter, as the case may be, are properly managed. These constitute the essentials in dairy management—essentials which may be attained in almost every particular by all dairymen. It is easy to see, that while, in the usual method of managing cows, very little profit can be realized, the results arrived at by the individuals named (and there are scores of similar cases) cannot fail to afford a very handsome profit from their labor. It costs scarcely any more to keep a stock of cows in good order throughout the year than to let them get poor, and then, by extra feed, raise them again to good condition. Now, we hold that three-fourths of the dairymen in this country may, by simply having warm and well ventilated stables, feeding and milking regularly, and treating their cows gently, increase their products considerably, without one

dollar of additional expense; and if a few bushels of grain or roots be added in the winter and spring, the *profit* will be greatly increased. Of the method of managing the milk and manufacture of butter and cheese, we have not room to speak in this article, but will endeavor to speak of some points connected with that subject hereafter. The cases to which we have alluded are not extremes, but are frequent in many parts of the State; yet not one in a hundred reaches the amount named in these statements.

The season for commencing dairy operations will soon arrive—indeed, the time for giving increased attention to dairy cows is now at hand; and we appeal to all, so far to consult their own interest, if they have no mercy for their animals, as to look well to the care of their stock during the coming spring. We also respectfully suggest to our agricultural brethren the propriety of endeavoring to increase the products of their dairy, as well as of all crops and productions of the farm, the coming season. We *can* improve in these as well as other branches of agriculture. Shall we not say that we *will* improve in these things? Let us not be disheartened by the assertion, so often thrust in our faces, that we now raise more than we need of agricultural products. Or if this is really so, let us keep fewer cows, and make from them the same quantity which we now make from a greater number. And so with our crops. Let our motto be, "The greatest amount of produce at the least expense." Profit is our object; and how shall we secure it, except by cheapening the cost of production?

E. COMSTOCK.

From the New England Farmer.

REPORTS OF ESSEX AGRICULTURAL SOCIETY.

To the Committee on Cows and Heifers:

GENTLEMEN: The cow which I offer for exhibition and premium is six years old. She calved the 21st of May, and has given milk as follows:

From May 21st to June 21st	1,469	pounds	4	ounces.
June 21st to July 21st	1,264	"		
July 21st to Aug. 21st	1,127	"	8	"
Aug. 21st to Sept. 21st	956	"	8	"
Total	4,817	"	4	"

We sell most of her milk; but in order to ascertain its quality, we have made butter from it, and find that it takes nineteen pounds of milk to one pound of butter.

Her keeping has been good grass feed, with the exception of seven weeks, when she had two quarts of shorts per day.

The said cow was raised by John Bartlett, of Marblehead, and has been owned by me two years and six months.

HENRY CREESY.

SALEM, *September* 24, 1845.

To the Committee on Cows and Heifers:

Gentlemen: I offer for your inspection my cow Flora, of native breed, six years old. The said cow calved on the 21st of last April. The calf was kept to her until the 13th of May. With what milk the calf left, and all after taking the calf from her, until the 20th of May, we made 20 lbs. 8 oz. of butter.

Beginning at the 20th of May, we kept an account of the milk, by weight, morning and night, for the four months following, which was 4,375 lbs. Butter from said milk, 211 lbs. 2 oz. From the 20th of May to the last day of June, inclusive, 84 lbs. 2 oz. In July, 52 lbs. In August, 43 lbs. Twenty days in September, 32 lbs. 2 oz.

From the 20th of May to the last day of June, she gave 1,597 lbs. of milk; in July, 1,115 lbs.; in August, 987 lbs.; twenty days in September, 676 lbs.

Average of milk through the four months, per day, $35\frac{105}{122}$ lbs. Average of butter through the season, four months, $20\frac{155}{211}$ lbs.

Manner of keeping said cow: After she calved, I commenced giving her two quarts of meal per day, until the last day of May; the 20th of May I put her to pasture by herself. Her pasture was good through June. The first week in July it failed; so I took her out and put her in an old pasture with other cows for three weeks, to let my pasture grow. I then put her back again in my pasture, and kept her until the 24th day of August, when I put her, with another cow, in new feed. I commenced giving her, the 30th of August, one quart of Indian meal and one quart of rye meal every night. She had no meal, roots, or any thing, only what the pasture afforded, from the first day of June until the thirtieth day of August.

WARREN AVERILL.

Ipswich, *September* 23, 1845.

ON BUTTER.

The Society's first premium for June butter was awarded to George W. Dodge, of Wenham.

Process of making.—The milk is strained into tin pans, where it stands from 36 to 48 hours. It is then skimmed, and the cream put into tin pails, standing on the bottom of the cellar. A little salt is put into the pails before putting in the cream, which, at the times of addition, is stirred. We churn twice a week. The buttermilk is thoroughly worked out by hand—no water being used for that purpose. In warm weather, the cream is lowered into the well the night before churning. Immediately after the buttermilk is worked out, the butter is salted with an ounce of ground rock salt to the pound, and in about 24 hours it is again worked over.

From the Albany Cultivator.

QUALITY OF MILK, &c.

One good cow, full fed, is worth more for the dairy than four ordinary half-starved ones. As an illustration of the truth of the above fact, we quote the following from an English publication: "A farmer some years since

kept *eighteen* cows upon a *common*, and was often obliged to buy butter for his family. The common was *enclosed*, which deprived the farmer of his pasture, and the same person supplied his family amply with the milk and butter from *four* cows *well kept*."

An ordinary cow, fed on young clover, should give, for the first three months after calving, from fifteen to eighteen quarts of milk per day, which will produce, if of good quality, $1\frac{1}{4}$ lb. of butter, or nearly 9 lbs. per week. Where the number of cows is greater, the average will be less; because, where there are only one or two cows, a deficiency in one of them is immediately noticed: the cow is got rid of, and a better one substituted.

The excellency of a dairy cow is estimated by the quantity and quality of her milk; and the quality of the milk is estimated by the quantity of butter that it will yield. Much depends on the quality of the food, but more on the animal. The writer has known one cow whose milk would not produce butter, and was never discovered while milked with the herd, but was soon apparent when separated and milked alone.

There is a simple instrument, called the lactometer, used for measuring the relative qualities of cream which the milk of different cows, at the different seasons of the year, affords. It consists of a mahogany stand, supporting six glass tubes of equal length and diameter. These tubes are marked ten inches from the bottom, and graduated down in tenths of an inch for three inches. Now, the milk from the different cows is poured into each tube, (which should be marked with the name of the cow,) and filled to the upper or ten-inch line, and the number of degrees the thickness of the cream occupies in each tube indicates the per centage. For example: if the bottom of the cream stands at one inch, it denotes 10 per cent. cream.

In a trial, with one of these instruments, of seven cows, six weeks after calving, in the months of March and April, we found they varied from 13 to $7\frac{1}{2}$ per cent. Out of the seven cows, the milk of two produced, after standing twenty-four hours in a temperature of 48 degrees, thirteen per cent. cream, one twelve, and another eleven per cent., in the same temperature; another, at 46 degrees, 9 per cent.; while two, at 40 degrees, stood at $8\frac{1}{2}$ and $7\frac{1}{2}$ per cent. The milk of four cows mixed, in a temperature of 48 degrees, marked 11 per cent. Now, it is well known, by those who have paid any attention to the subject, that temperature has considerable influence in raising cream, which may, in part, account for the low per centage of the two last-named cows; but in other trials we have found they varied from 7 to 20 per cent.

After comparing the accounts, given in a variety of places and situations, of the average quantity of milk which a cow gives when kept alone, and well fed, as they generally are, with a full supply of food, such as they relish, to the extent of their appetites, the result is, that it greatly exceeds that of our best dairy herds, and the quantity of butter made from a given quantity of milk is also greater.

I am aware that high feeding of milch cows on grain is not generally believed to be profitable; but I am satisfied that the cows would give milk nearly the whole year, be made good beef at the same time, and their calves would be much more valuable.

If cows are ever allowed to fall away low during winter, in vain shall we hope to obtain an abundant supply of milk by bringing them into high condition in the summer; for, if a cow be lean at the time of calving, no management afterwards will ever bring her to yield, for the season, any thing

like the quantity of milk that she would have done had she been all the while in high condition.

C. N. BEMENT.

AMERICAN HOTEL, ALBANY, *August*, 1845.

For the Louisville Journal and Dollar Farmer.

DESCRIPTION OF THE LARGE DAIRY ESTABLISHMENTS THAT SUPPLY THE PRINCIPAL CITIES OF GREAT BRITAIN WITH MILK.

Having read of late, with much interest, (in the eastern agricultural papers,) an account of various well conducted farms, I am induced to think an abridged description of some of the great "lactarys," as they are fashionably called, of the old country, from notes taken several years since on a tour with the late Dr. Ratcliff, the excellent and efficient secretary to the "Farming Society of Ireland," will be received with some interest by your readers, and it possibly may be also instructive. My observation convinces me there is much in their management that could be well and profitably adopted by our dairymen in this country.

The two largest dairies in the world, containing the greatest number of cows giving milk at the same time in the same establishment, are in London, situated near and within sight of each other, at Islington, formerly a part of the suburbs, but now a well built and densely populated portion of that great city: the one established more than half a century ago by the late Mr. Rhodes, and still conducted by his sons; the other established about the same time by the late Mr. Laycock, and now in possession of his sons also.

Rhodes's, which I shall first describe, is the most complete of the two. The number of cows now kept there varies from seven hundred up to nine hundred. Mrs. Rhodes, who, after her husband's death, took the whole management of the concern for some years upon herself, told me that she several times attempted to have one thousand cows milked, but that the number was never completed in the morning; that, before night, death or some other accident occurred among them to prevent her accomplishing that desire. The ground on which the buildings are placed is a slope of some three or four acres, fronting the east. The sheds run with the slope for the drainage, and more easily wheeling off the manure, as well as for supplying water for the cows through small cast-iron troughs, which are fixed in the walls at the heads of the cows, in such a manner that one trough may be supplied from the other the whole length of the house. The sheds are twenty-four feet wide and ten feet high; tiled roof, with rising shutters for ventilation, and panes of glass glazed into cast-iron skeleton tiles for light. The floor has a slight fall to a gutter along the centre; a range of stalls, each seven and a half feet wide, for two cows to stand in, runs along the sides, to which they are fastened by chains and rings running on upright iron rods in each corner. A trough, formed of Welch slate, bedded in cement, its upper edge eighteen inches from the ground, is fixed at the head of each animal, to hold its food. The sheds are placed adjoining and parallel to each other, with openings in the walls opposite each cow, one foot wide and four feet high, in which is placed the iron trough to contain the drinking water, calculated to serve two cows in different

sheds, but opposite each other; which water is supplied from one large cistern by pipes. Each iron trough has a wooden cover, which is shut down during feeding time, to prevent the water being dirtied. At the upper end of the shed is the dairy, consisting of three rooms: the one a measuring room, where all the milk that is sold and goes out is first measured; the other a scalding room, with boiler and fireplace; and the third, a room where all the surplus milk is strained up and set away for cream and butter. At the lower end of the sheds are two yards, surrounded by sheds also; the one for fattening the cows off when they become dry, and the other for store and breeding pigs. The pigs consume the skim-milk remaining on hand, which is kept in a well, made of brick, laid in cement, twelve feet deep, and six and a half in diameter, in which it soon becomes sour, and then fed to the pigs, as it is well known to be more nourishing when given in that state than when sweet. The principal stock of pigs are breeding sows, as the sucking pigs sold for roasting are found to be much the most profitable. The dung is all emptied into a pit for that purpose, off a platform at the bottom of the yards. Within the last ten years there have been constructed in the rear of the sheds several large pits ten feet wide, twelve feet deep, and twenty feet long, made of brick, bedded in cement, into which are packed several months' supply of brewers' and distillers' grains, which form the chief food for the cows, and which can only be had during the winter months. The grains are firmly *tramped* into those pits, and each layer, of about one foot in thickness, is well salted; when filled, the top is covered over with boards, and on those is put a thickness of earth, compactly beaten down, sufficient to perfectly exclude the air as well as the frost. Grains packed in this way have been opened in four or five years, and found to be fresh and good food, and as eagerly eaten by the cows as those that had just been carted in from the brewery. There are also on the premises a large stock yard, sheds, and pits for roots and straw, a large room for cutting hay and clover into chaff, cart-sheds, stables, a neat and spacious counting-house, with a large, well ventilated room overhead, containing several iron bedsteads, with hair mattress and pillow to each, where the regular work hands belonging to the establishment, who are single men, sleep.

The cows in this establishment are all bought, newly calved, in the cow market, held in Islington every Monday. They are kept as long as they continue to give *not less than two gallons of milk a day*, and are then fattened off for the butcher on oil-cake, grains, and cut clover hay. All breeds are to be found here to some extent, but the short-horns are preferred, and are greatly in the majority; they are generally found to be more abundant milkers. The shortness of their horns, too, admits of their being placed closer together; and another reason is, because this breed is more frequently brought to market than any other. The Ayrshire breed was tried to some extent, and highly approved of, as giving very rich cream, fattening in a very short time when they left off giving milk, and particularly for producing a quantity of beef which sold much higher than that of the short-horns; but the difficulty in procuring this breed was so great, that they abandoned the idea of keeping them. The length of time during which a cow, treated as in this establishment, continues to give milk, varies from six months up to two years, the large majority overgoing twelve months. The treatment in this establishment differs from that in most others. The cows are *never untied* during the whole time they remain in the house, having clean

fresh water to drink, constantly before them. They are kept very clean; the sheds are well ventilated by the openings in the roofs, which are certainly far preferable to the usual horizontal entrances for air, by holes through the side walls. The principal food of the cows, as in all other London dairies, consists of grains; that is, malt after it has been used by the brewer or the distiller. Distiller's wash, which is the remainder, after distillation, of a decoction of ground malt and oaten meal, is also given to the cows, but more frequently to those that are fattening than to such as are in milk. The average price of brewers' grains is about fourpence or eight cents per bushel; distillers' grains, on account of the meal which they contain, about double, or sixteen cents per bushel; the wash usually sells at sixpence, or twelve cents, for thirty-six gallons. Salt is given at the rate of two ounces to each cow daily in this establishment, mixed with the grains given before milking, at 3 o'clock in the morning, and about 2 o'clock in the afternoon. A portion of green food or roots is supplied alternately with the grains; and in winter, when tares or green grass cannot be procured, after the potatoes, turnips, or mangel-wurtzel have been eaten, a portion of hay is given.

The produce of Rhodes's dairy is entirely milk and cream for private families and for public hospitals. A number of public institutions are supplied directly from this dairy by contract. Private families are supplied by milk dealers, who have what is called milk-walks; that is, a certain number of customers whom they supply twice a day; they are thus enabled to ascertain the average of what their customers require, and they contract with Messrs. Rhodes for this average. The latter calculate the number of cows sufficient to give the dealer the supply wanted, and this number the dealer undertakes to milk twice a day—at 3 o'clock in the morning, and at 3 o'clock in the afternoon. The milk is measured to the dealer; and should he have milked more than his quantity, it remains with the dairy; but should the cows be deficient in quantity, it is made up from the milk of other cows milked on account of the contracts of the establishment. As the supply of the cows and the demand of the dealers are constantly varying, large quantities of milk remain on the dairyman's hands, frequently as high as seventy to eighty gallons, which is strained up in shallow earthen vessels for cream. The cream is churned, the butter sold, and the skim-milk, as well as the buttermilk, is put into the milk-well for the pigs.

The management of the whole is committed to three persons: a clerk, who keeps the books, collects the debts, and pays and receives all moneys; a man who superintends the feeding and treatment of the stock, and who has the general care of the premises; and a woman who measures the milk to the dealers, and superintends the dairy. The cows are all purchased and sold by a regular salesman.

Laycock's dairy is also at Islington, nearly on the opposite side of the way to Rhodes's, but stands on a greater number of acres. The number of cows kept in Laycock's is about the same as that kept by Rhodes, but in treatment they differ some little. I will notice only those particulars in which this establishment differs from Rhodes's. The cows are fed in the same way, with the exception of not getting any salt on their grains, but the hay is salted when put in the rick. They are turned out once a day to drink from troughs in the yards, remaining out from half an hour to three hours, according to the weather and season of the year. From the end of June till Michaelmas, the cows are turned into the fields from 6 o'clock

in the morning until 11, and from about 2 o'clock in the afternoon until about 3 the following morning. The remaining hours they are in the sheds, for the purpose of being milked. The cows in this establishment are, on an average, kept in use longer than in Mr. Rhodes's; those which become dry are fattened in the same way, with the addition of boiled flax-seed, which is found to be a valuable assistant. The mode of using it was to me quite novel, as was its use at all for the purpose of fattening. It is boiled in a common boiler, and, when reduced to a pulp, let out into large wooden cisterns by tubes, where it was mixed with clover chaff, roughly cut, and sometimes with grains; and, when cool, given to the cows, who eat it in this way with great avidity. In this establishment those cows which are good milkers are allowed to take the bull, for which purpose eight bulls were kept on the premises. The usual period of keeping the cows is from four to five years. The calves are sold in Smithfield cattle market, the market next after they are calved, to those who make it a business to take them to the country and fatten them for the butcher. There are three extensive farms belonging to this establishment but a few miles distant, at one or other of which the cows in calf are kept when dry. The hair of the tails is kept closely trimmed off, to prevent the risk of dirtying the milk, and their bodies are curried over once every day. The pigs, in addition to sour milk, get also ground linseed and grains.

In addition to this dairy establishment, Mr. Laycock has a series of enclosed yards, about half an acre each in size, with open sheds sufficient to shelter from eight thousand to nine thousand head of cattle, which are appropriated to taking in stock for the nights previous to the days on which Smithfield market is held, which are on Monday and Friday of every week in the year. For this purpose the situation is admirably adapted, lying on the great north road, and being within a short and straight drive of the market, which, singular enough, is situated in the very heart of the most thickly populated part of that immense city. Those layers and this dairy establishment may be considered as a central farm yard to the three hay-farms, which they amply supply with immense quantities of the finest manure for top dressings.

The whole is under the management of the two brothers, assisted by a clerk and a very active dairy-maid. The proprietors of those, the two most extensive milk establishments in the world, are near and intimate friends and neighbors from their birth, are on the best possible terms, and have as free recourse to either establishment as though they belonged to the same person. They frequently compare notes as to the management and expenses, and they both still rigidly adhere to their own particular management, each contending for his superiority, and offering to prove it by a reference to his books. All I can say is, that both are managed with great care and attention, systematized in every department. They have been carried on successfully and profitably for more than half a century by the fathers, and subsequently by their sons; and I have no doubt that, in a century from now, whoever lives to see it will find the same successful operation, and both under the management of the great grand-children or immediate descendants of the original founders.

The Metropolitan dairy is the next largest establishment of the kind in London; it is situated in the Edgeware road, (the northwestern suburb of the city,) and was founded some twenty-five years since by the late Mr. Rhodes. It was sold by him, some few years after, to one of the bubble compa-

nies of that day, from which its present name is derived. By them it was sold to Mr. Wilberforce, and is now his property. It stands on about one acre of ground, and is calculated to contain about four hundred cows. The cow houses are in parallel ranges, twenty-four feet wide, and side walls eight feet high. The space allowed here for each cow is three feet nine inches, and the greater number of the cow-houses are without stalls. As in Mr. Rhodes's establishment, the cows here are never untied, except to remove them to the fattening sheds, or to send them to the country to remain till calving time. A cow so treated seldom produces more than two calves, remaining, after each calf, an average of eighteen months in milk.

The cows are milked at 3 in the morning and 2 in the afternoon, and the milk disposed of to dealers as before described. The food is principally grains, which, instead of being kept in pits in the open air, as at Rhodes's, are preserved in the cellar of a large building about fourteen feet deep, and are covered, when packed down, to the depth of one foot with cow dung, to protect them from the influence of the air. Dry hay is seldom given in this establishment, the chaff of clover hay being always mixed with the grains or wash. The cows are never turned out to water, but, from a large cistern, pipes are conducted to every cow house, and at certain hours each day the water is turned into the manger, which is on a perfect level; and it runs slowly past each cow, so that she drinks at pleasure. When any cow gets sick, she is bled, and is purged by giving her one pound of *Epsom* salts, with two ounces of flour of sulphur, and an abundance of warm water. The mode of treatment seldom or never fails. Four bulls are kept for the cows; and, as they become dry, or nearly so, they are sent out to a grass farm till calving time. The quantity of salt given the cows in their food here does not exceed one ounce daily, on account, as they assert, of its drying quality; a complaint I never heard made but in this establishment, and with which I cannot concur. The manure of this establishment is disposed of in a singular and interesting manner: all the fluid part is discharged by sewers into a large brick cistern, laid in cement, and sold by the hogshead to the hay farmers in the neighborhood to manure their meadows with, which is done with the common watering cart used for the streets. The solid manure is compressed into small squares or cakes by an hydraulic press, and is all shipped to Norfolk and to Yorkshire; the computation is, that a two-horse cart load of dung is reduced to the size of a cubic foot by this means.

There are many minor dairy establishments in and about London, none of which are worthy of notice, save one at Little Acton, about five miles from Hyde Park corner, under the sole management of a maiden lady, (Mrs. Cook,) and stands on a farm of two hundred acres, the whole of which is devoted to meadow. There are two hundred and fifty cows in three sheds, standing head to head, with a passage of five feet between the troughs. The cows here are never untied except for about two months in the autumn, when they are let out after each milking for about two hours, to fill themselves off the after grass. Water is supplied to them in their troughs twice a day, through pipes from a fine spring adjacent. Grains, with roots and other green meat, are the principal food of the cows; and Mrs. Cook considers it much more economical to turn the entire of her farm to meadow, and with the extra produce to purchase the other food wanted for the cows, rather than multiply her expenses and increase her own trouble and cares, by placing it under a system of agricultural courses. There is

no doubt but Mrs. Cook's establishment, for its size, returns, under her peculiar management, a better profit than any other in London or its neighborhood. Her cows are all milked by her own men, at 2 o'clock every morning and 2 every afternoon, and the produce sent in six-gallon block tin cans, on a superior two-horse "C" spring carriage, (with scarcely any motion to it,) to a West-end milk dealer in Edward street, Portman square, who contracts for the whole. This establishment is characterized, beyond any other I have ever seen, by its great neatness and cleanliness, both as regards the premises, the cattle themselves, and all those who attend upon them.

It is worthy of remark, that in no instance is there to be found a milk wagon used for the delivery of the milk to the families; it is always carried in tin cans, suspended from a wooden yoke that fits over the shoulder, by either women or men, who generally distribute in this way from twenty to twenty-four gallons within two hours. It is considered—and with some truth, too—that jolting the milk in wagons has an injurious effect upon it; certainly tending to make it sour, and rendering it entirely unfit to set for cream. This mode of delivery causes the milk dealers to have a better understanding amongst themselves as to the distribution of their customers, the same person being generally found to serve with milk every house that takes any in the same street, and consequently rendering the labor much less.

This communication, which is already longer than I intended, warns me to reserve for my next a description of Booth's extensive feeding-house, attached to his gin-distillery, and of the Glasgow and Dublin dairies—both better managed than the London ones, I think—as well as a glance at some of the Dutch dairies, which are under still better management than either.

Wishing to contribute to the interest of your paper all in my power, I beg your acceptance of this communication, with the respect and good will of

A Farmer.

APPENDIX No. 25.

CATTLE, &c.

[From proceedings in the New York Farmers' Club.]

SOILING CATTLE.

Mr. Edward Clark—*Sir:* As to soiling, I understand it to apply to all green food that is raised for the purpose of feeding to stock in summer or winter—the stock being kept up and fed on the same. I consider the root crop as one of the only sure means in our latitude of carrying out the principle through the season; I therefore have been in the habit of raising roots for my stock for several years, and I do not think I could do well without them. I will therefore state, as nearly as I can, my mode of raising them, and feeding, &c. I will name them in the order in which I estimate them for feeding to stock. Carrots I consider the most valuable. I feed them to all kinds of stock, and consider them better for my horses than oats; and for my milch cows, in winter, they not only give the butter color, but flavor equal to summer-made butter. I raise them in drills, the rows about 20 inches apart, and the carrot in the row say from four to six inches; mangel-wurtzel in drills, two feet apart in the row, and one foot in the drill; sugar beet the same distance; ruta-baga two feet apart in the row, and about nine inches in the drill; and common turnips I sow broadcast as follows: say in June, I find some pieces in my lots intended for mowing, that the grass has winter-killed, or in some way is destroyed; these pieces I plough up, taking care to turn them over as well as I can, sometimes before and sometimes after mowing, but always in time to sow and re-seed with grass by the 20th July. I roll my land, and harrow it well the same way I plough it, and put on about 15 cords of manure to the acre, (barn-yard manure;) I harrow until all is well mixed; I then sow my turnips, say one-half pint of seed to the acre; it is my wish not to have the seed nearer than nine inches of each other; in doing so I give my grass seed a chance to take root. At the time of sowing my turnips, I sow a compost, prepared as follows: ashes, 15 bushels; bone-dust, five bushels; plaster, one bushel—per acre; in this way I always raise good turnips, and, I think, at a trifling expense, as all that was done was with a view to re-seed the land, &c. As to the other root crops, the same rule as to manuring will apply to them, but the ground must be made mellow to any depth you please—the deeper the better. I use the same compost, in the drills, for all my roots, taking care at all times to apply it in a moist condition. I raised the last season the white Silesian carrot, at the rate of 960 bushels to the acre; but I prefer the orange carrot. As to feeding roots, I feed them to my fat cattle, cows, horses, and hogs, in the raw state; nor do I think it advisable to cook them for any animal except the fatting hogs. I then boil them and mix provender, and feed when soured. Quantity per day: I feed to my cattle say three-fourths of a peck, to be fed at two different times, say morning and evening; my milch cows, one-half bushel per day; my store hogs, of beets say three pounds per hog, and one gill of corn per feed. By feeding in this way, I have always found my stock to

improve, and I never have had them to scour or be injured in any way from their feed on roots. I continue my feed on roots to my fat cattle until about the 1st of January; I then commence feeding on meal, made with corn and cob, and continue the roots, at discretion, in smaller quantities. I should not have thought it necessary to state the quantity I feed at a time, but for the reason that some gentleman at your meeting, above alluded to, condemned the root crops; all I can now say is, that this is not my experience, nor do I believe it will be their's, on a fair trial.

With respect, I remain yours,

WM. MAK'INSTER.

MIDDLETOWN, CT., *April* 4, 1845.

The Chairman.—A bushel of carrots, well cut up by a proper root cutter, is as good as a bushel of oats for a working-horse. I have tried the experiment fully and satisfactorily: I have fed twelve quarts of sliced carrots, instead of twelve quarts of oats, to a horse, the whole winter, and found no difference in the results. I gave hay with the carrots as we do with the oats. The carrots cost about ten cents a bushel, and the oats near thirty cents a bushel.

Dr. Underhill.—The general average price of oats is about thirty-five cents a bushel.

The Chairman.—Carrots are beneficial to horses that have the heaves. Others have practised as I have with like satisfactory results. I have raised three hundred and twenty-five bushels of carrots on three-eighths of one acre. I manured with decomposed peat and ashes. I sub-soiled the hill. The white carrot is good; gives rather greater yield than the orange carrot; it grows more out of ground, and is easier to gather. I do not attach much value to the ruta-baga; it has, however, one advantage—it may be sowed late, and upon any vacant spots in a field, and is so far clear gain.

From the Cultivator.

WINTER FOOD FOR DOMESTIC ANIMALS.

In most parts of the northern States, a very large portion of the year requires the feeding of dried or stored food to domestic animals. Usually one-half of the last month of autumn, the three winter months, and at least two of the spring months, must be passed without the aid of pasture, throughout the more northern regions of our country, amounting to almost half of the entire year. It hence becomes one of the most important of all questions in farming—what are the cheapest and best kinds of food for the subsistence of domestic animals through this long and costly period?

The article which stands at the head of the list, as being the most largely used as well as the most important every way, is meadow-hay. But auxiliaries are needed; not only because the hay crop is often greatly diminished by drought, but even when abundant, a mixture of other substances contributes to the health, comfort, and thrift of the animal. Greater cheapness, too, is attained by a portion of other kinds of food. An examination and comparison of these hence become a matter of considerable importance.

In addition to hay, may be mentioned (as among those substances which are either in common use, or should be) carrots, ruta-bagas, straw, beets, potatoes, and grain. The propriety of the use of these may be judged with tolerable correctness, by taking their respective nutritive values, together with their cost in raising, and comparing them thus with hay. In the following table we have taken a few of the more commonly cultivated roots, and deduced their nutritive value from the actual experiments of a considerable number of distinguished agriculturists, the mean or average of the results they arrived at being taken. The figures indicate the number of pounds of each needed, to be equal to 100 pounds of hay.

Carrots - - - - - - -	276
Ruta-bagas - - - - - -	300
Mangel-wurtzel - - - - - -	317
Potatoes - - - - - -	201
Common turnips - - - - -	494

It will be perceived that potatoes are the most nutritive, carrots next, then ruta-bagas and mangel-wurtzels are nearly equal, while common turnips are far behind the rest. Then as to the expense of raising. The same degree of fertility in soil will give about 250 bushels of potatoes, 500 of carrots, 600 of ruta bagas, and 700 of mangel-wurtzels. This is mere estimate, but is probably not far from the truth. The cost of seed and planting is greater for the potato than the other crops, but the after culture rather less; on the whole, the expense of raising an acre of each will be nearly equal. The cheapness of seed and ease of sowing are in favor of ruta-bagas, but on cloddy soils this advantage is more than balanced by danger from the turnip fly. It is understood, as a matter of course, that in these estimates the best culture is to be given—that is, all the roots but the potatoes are sown in drills, from two to two and a half feet apart—not more; that they are hoed as soon as they are up, or before two inches high, which not only greatly reduces the labor, but allows an early and vigorous growth; and that clean, well tilled, and fertile land is selected for them, and not rich waste land, loaded with the seeds of millions of weeds, which, without the cost of much labor, get the ascendency, and choke down the young crop.

Taking all these circumstances into account, it will be perceived that carrots, ruta bagas, and mangel-wurtzels stand nearly on equal grounds as to merit. But the far greater avidity with which horses will eat carrots, the excellent butter which results from their use when fed to cows, and the little injury they receive from frost, even when the crop or a part of it is left to winter in the ground where it grew, give this crop most eminently the preference.

Now for the cheapness of roots as compared with hay. A ton of hay, according to the experiments already mentioned, is equal to 5,500 pounds of carrots, which, at 60 pounds to the bushel, would be 91 bushels. One acre of carrots, then, or 500 bushels, would be equal to 5½ tons of hay. According to our own experience, such a crop may be easily raised and harvested for fifteen dollars, which would place the carrots as a cheaper food than hay, if the hay were only three dollars a ton. But the superiority of the condition of horses and cattle, when fed freely on carrots, with hay, is an additional advantage.

Straw.—The following shows the comparative nutritive properties of straw, by indicating the number of pounds needed, to be equal to 100 lbs.

of hay. But it must be observed that these results will vary greatly with the ripeness or freshness of the straw, and other circumstances connected with its growth or condition.

New wheat straw	272
Oat straw	166
Barley straw	176
Pea straw	169
Clover hay	94

But as the quantity of straw is wholly dependant on the quantity of grain raised, and is in fact only a secondary crop, the amount which each farmer possesses can only be controlled by economy in saving what he has, which cattle will eat freely if mixed with hay and chopped, or alone, unchopped, if well salted.

There is another item of cheap and nutritious food in the shape of cornstalks, sown for fodder. The value of common cornstalks, raised for the grain, depends greatly on the quality, and the amount which cattle can consume without refuse, depending on the size of the stalks, variety of corn, &c. But when the corn is sowed thickly for fodder alone, all is consumed, and a ton is probably fully equal to a ton of hay. Five tons *at least* (according to repeated trial of the writer) may be raised as follows, on an acre of respectable fertility—say rich enough for 500 bushels of ruta-bagas. Plough and harrow as usual; furrow one way two and a half feet apart, with one horse; strew three bushels of corn to the acre along these furrows, from a basket; cross-harrow to cover the corn; pass the cultivator two or three times along the rows, but not hoe them; and mow with scythes, dry, and draw in. The whole expense, including interest on land, need not be more than twelve dollars; placing the cornstalks, which are more palatable for cows than any hay, at less than two and a half dollars a ton. There is no exaggeration about this, but it is the result of repeated trial.

An objection is made to the extensive use of roots, on account of the difficulty of keeping them and feeding them out through winter. But this objection must disappear at once if a good *root cellar*, close at hand, is constructed. The farmer must have a barn for his hay, and he must have a cellar for his roots; the latter need cost no more than the former. The objection, therefore, should vanish.

Another objection is, that animals do not like roots—will not eat them or it is hard to teach them to eat. This difficulty may be variously obviated. Cattle scarcely ever refuse any kind of roots. Horses and sheep reject them at first; but perseverance, short allowance, or chopping up fine and mixing with meal, and then gradually returning to a coarser chopping, and a diminished quantity of meal, will usually do the work. We have taught old horses, which totally refused ruta bagas at first, to gnaw down whole ones with great avidity, and a neighbor regularly wintered his store hogs mainly upon them without cooking.

The comparison of different kinds of grain with hay, according to the before-mentioned experiments, is as follows:

Corn	52
Barley	53
Oats	67
Peas	47
Wheat	46

Eighteen bushels of corn will therefore be equal to one ton of hay. The farmer can judge, from prices, whether a loss or gain would result from a free or scant use of this grain. He can also apply the same rule to other kinds of grain.

On reviewing these estimates, it will be perceived that the greatest loss which farmers usually sustain is from the neglect of the free culture of root crops, and of cornstalks for fodder. An abundance of roots at hand would enable the farmer to save one-half of the hay usually fed to cattle, or one-quarter of the whole cost of feeding them. An equal saving would result from the use of cornstalk fodder. Taking, then, these two articles together, and not forgetting the increased amount of butter and milk, and the improved condition of the animals, it is probable that one-half the expense of wintering cattle would be saved by an improved system; and perhaps equal advantages would result in the keeping of sheep and horses. Making allowance for difficulties in introducing such a system in poor soils or unfavorable localities, and calling the gain only one-quarter, what would be the total gain in the State of New York alone? There are in the State, according to census, about 470,000 horses, 1,900,000 cattle, and 5,000,000 sheep; the total expense of wintering them cannot be less than twenty millions of dollars, at a low estimate: one-quarter of this would be *five millions*, saved every year in one State.

The saving which we have made ourselves, and which we have seen successfully practised by others, satisfies us that these estimates are very moderate, and that this conclusion arrived at is not speculation, but positive and existing fact. The great assistance which such a system would lend to fertile and compact culture, instead of skimming and surface work, by increasing manure and fertility, should induce every enlightened agriculturist to labor assiduously for its general extension.

APPENDIX No. 26.

SHEEP, WOOL, &c.

From the Am. Agriculturist.

SHEEP HUSBANDRY IN KENTUCKY.

I am highly gratified at the various indications I have observed in the American Agriculturist of a disposition favorable to an extension of sheep husbandry in the United States. This is a subject in which I have always taken a deep interest, because I believe it will not only greatly promote the agricultural interest, but tend, in an eminent degree, to advance the wealth and prosperity of the whole Union. The difficulty of finding an *adequate* market for our rapidly increasing agricultural products, renders it necessary that we should avail ourselves of as many new sources for the *profitable* employment of *land* and *labor* as possible. Nothing, in our present circumstances, is better calculated for this purpose, than sheep husbandry. We have *land* in great abundance, whilst *labor* is comparatively scarce. Sheep husbandry requires much land, and is attended with the advantage of requiring *comparatively* few laborers, and, instead of exhausting, tends greatly to fertilize the land thus appropriated. Sheep husbandry may be practised in almost every part of our extensive country; but doubtless some portions of it are better adapted to the business, and it can be carried on more economically than in others. Without pretending to speak disparagingly of other parts, allow me to set forth the claims of Kentucky as eminently adapted to this highly useful branch of agriculture. To illustrate its fitness for this purpose, suffer me to refer to my own practice in a small way.

For some years after I commenced raising sheep (my cleared land and pastures being then very limited) I *housed them* during the winter months, and fed them with hay, sheaf-oats, and occasionally with corn. But when my cleared land and pastures became more extensive, I found that I could winter my sheep to better advantage by suffering them to run on blue-grass pastures, kept in reserve for them, hauling out, and scattering on the turf, corn fodder, when the grass became too short or was covered with snow. This mode of feeding required less labor, and was less expensive than housing them; and experience soon taught me that my sheep passed through the winter in better condition than when housed and fed on hay and grain.

I have now about three hundred acres of cleared land, nearly one-half of which is in meadow, clover, and blue-grass, (*poa pratensis*,) and the other half reserved for cultivation in corn, wheat, hemp, &c.; and one hundred and fifty acres in woodland, the greater part well cleared up and sown in blue-grass. I have been taught by experience, recently, that sheep will do remarkably well on the rankest clover, which will enable me in future to keep more of my blue-grass pastures in reserve for winter feeding. During the last fall (the season being favorable) my clover fields furnished my flock, of somewhat less than four hundred, sufficient pasturage till the month of January; and they have been since kept on my blue grass pastures, without the necessity of feeding, except some four or five days, when

the ground was covered with snow; and there is still grass enough to carry them through the residue of the winter.

The low price of hemp, and agricultural products generally, has induced me to sow down much of my cleared land in clover, which will enable me to keep double the number of sheep I now have, without interfering with my farming operations; and when I get the whole of my woodland cleared up, and set in blue-grass, I expect to extend my flock to one thousand sheep. Thus you see we are neither under the necessity of incurring the expense of erecting buildings to shelter our sheep, nor of raising grain or hay for their food, nor even to employ laborers to feed them, except during the short time it may become necessary to haul out fodder for them when the ground is covered with snow. And in a single day enough may be hauled out on sleds to last them a week or more.

It is argued by some that our rich lands are too valuable to be appropriated advantageously to sheep husbandry. There would be much force in this objection if they were entirely appropriated to that purpose; but not so when sheep husbandry is combined with large hemp and corn crops. Hemp has hitherto been a profitable crop, though now it is too low to justify its extensive culture; and large corn crops are necessary with a view of raising horses, mules, cattle, and hogs. There is no system of husbandry so well calculated to prepare our lands for large products of corn and hemp as feeding sheep on our clover lands. I had supposed, till I made the experiment, that sheep would not do well on rank clover.* To satisfy myself on this point, I put about one hundred and fifty wethers on a clover field, when in flower, early in May. The clover was at the time nearly as high as the sheeps' backs, (Merinoes.) I kept them on this during the whole summer, and in the fall they were fat enough for the butcher. It is true, they trod down much of the clover; but as I had an abundance of pasture, this was an advantage, as it left a thick mat of grass on the ground, intermingled with the droppings of the sheep, distributed with much regularity. This thick covering prevented a loss of manure by washing rains, and rapidly brought on a second growth of clover, which furnished my whole flock with an abundance of pasture till the early part of January. The season was, however, unusually favorable, and hence the clover pastures lasted two or three weeks later than usual. In future, I intend to keep my sheep entirely on my clover fields from the time they are in flower, and thus I shall be able to keep in reserve a greater supply of blue-grass for winter feeding.

But it is not upon our high-priced rich lands alone that we can carry on sheep husbandry to advantage. Kentucky has a belt of hill and mountain country, bordering on the Virginia line on the east, and on the rich lands of the State on the west, averaging about seventy-five miles in width, extending from the Ohio river and Big Sandy, latitude 38° 30′, to the Tennessee line, 36° 30′ north. The whole of this region is admirably adapted to sheep husbandry; the most northern part but a few minutes north of my residence, and extending about two degrees farther south. The lands

* Feeding sheep on clover, especially when fattening them, is quite a common practice in Europe and in the northern States of America. They do extremely well upon it; and, if accustomed to it gradually, there is no fear of hoven, the only thing to dread from rank clover pasture. By good feeding, sheep may be pushed forward in their growth and breeding one year. They will, moreover, be larger and finer in the carcass, and produce a greater weight of wool, and that of a superior quality.

are very cheap—the State price of those not yet appropriated only five cents per acre, and those purchased second-hand, more or less improved, may be had from 25 to 50 cents per acre, and still less when unimproved. This country in a state of nature furnishes, during the spring, summer, and fall months, a fine range for sheep, and is susceptible of great improvement by clearing up and sowing the cultivated grasses for winter feeding. This whole country is finely adapted to the Spanish mode of sheep husbandry. Very large flocks might be driven to the mountain region, some thirty to sixty miles from the rich lands, immediately after shearing time, grazed till late in the fall, and then brought back to be sustained during the winter on the luxuriant blue-grass pastures of the rich lands of the interior.

A very intelligent friend, residing in the southern part of the above district of country, speaks of it in the following terms: "One of the strongest proofs of this region of country being favorable to the growing of sheep stock is, that we are situated in the same degree of north latitude with the sheep raising parts of Spain—Leon, Estremadura, Old Castile, &c.—only that our mountains are more richly and abundantly clad with luxuriant wild grasses and fern, pea vine, and shrubbery, than the mountain regions of Spain, where they raise such abundant stocks of sheep. Wayne county, with a few adjoining counties, affords more fine water-power than any country of the same extent that I have ever known; and for health, and fine, pure drinking-water, no country excels it on the face of the globe. Now is the time to commence the business of sheep husbandry, whilst land can be got almost for nothing. It is worthy of remark that our sheep, which are suffered to roam and graze in the mountains altogether, produce about *one-fourth more wool at a shearing than the sheep that are raised and grazed altogether on our farms, and of much better quality.*" In another part of his letter he says: "The tops of the mountains of Spain are sterile, without verdure, producing no food for sheep, or other animals, to graze on. Our mountains are quite different. They are thickly clad from bottom to top, and all over the top, with fine, rich wild grasses and shrubbery of every variety, for stock to graze on. In the midst of our mountains are to be found a great abundance of salt-water and stone-coal of the finest quality, together with a great variety of mineral waters and pure springs."

Another friend, residing in Knox county, writes to me: "My sheep upon my farm, adjoining Barboursville, do not thrive, even with pasture and winter food, like the sheep in the extremities of the county, which have neither pastures nor winter food, except what they get in the woods. Without cultivated grasses of any description, sheep will live and do well all the winter, subsisting on the spontaneous growth of the country."

Another friend, residing in the northern portion of the above-described mountain region, writes that "the counties of Carter and Lawrence, and the eastern portion of the State, are admirably adapted to sheep husbandry. There are several flocks of sheep in this neighborhood that thrive and increase wonderfully, *running at large*, at little cost or trouble to the owners. Many flocks have no other reliance, during the winter, but what they get in the woods. The great advantages of this country for sheep husbandry are, the cheapness of the land, its adaptation to grasses, grain, and roots—its heathfulness. Sheep delight in mountain or hilly land—the natural evergreens and shrubbery upon which sheep can feed and subsist on in winter; though it is not safe to rely altogether upon these."

I could give many other extracts from letters addressed to me by highly intelligent gentlemen, residing in the mountain districts above described, to show its admirable adaptation to sheep husbandry, but I refrain from doing so, for fear of running this communication to too great a length.

There is also a strip of low-priced land bordering on the Ohio river, in the counties of Bracken, Pendleton, Campbell, Kenton, and from thence to Louisville, finely adapted to sheep husbandry; but I have not space to go into a description of it.

A few remarks as to the probable future market for wool will conclude my letter—already, I fear, too long. The returns of the late census show that the number of sheep in the United States in 1840 was a fraction less than 20,000,000. Twice this number would probably not furnish more wool than would be needed by a population of 17,000,000, if we were to manufacture all our own blankets, carpets, and every other description of woolen fabrics. The period is not very distant when this will be done, with the exception of some very fine goods. We shall then need about 100,000,000 pounds of wool for a population of 17,000,000, and in that proportion for home consumption, even supposing none should be exported. Now, as our population increases (as past experience demonstrates) at a compound ratio of three per cent. per annum, we shall have a population of 34,000,000 in the year 1864; 51,000,000 in 1878; and 60,000,000 in 1888.* We shall need at these respective periods two, three, and four hundred millions of pounds of wool. If we estimate sheep, upon an average, to produce two pounds and a half of wool per head, we shall require, in the year 1888, (a little more than forty years hence,) 160,000,000 of sheep. This view of the subject, without looking to a foreign market, holds out a strong inducement to engage in sheep husbandry.

A. BEATTY.

From the Nashville Agriculturist.

SHEEP IN THE CUMBERLAND MOUNTAINS.

After having spent part of the years '43 and '44 on different parts of the Cumberland mountains—*the part of Tennessee more particularly recommended* by all writers in your journal, and others, for sheep walks—I have, since last fall, settled on a portion of them near Jasper, Marion county, and will, as briefly as possible, give you the result of my experience, which will, I believe, fully remove any erroneous impressions hitherto made.

First, as to climate. The extreme salubrity of the mountains makes them the general refuge of the sick. Sheep here are remarkably healthy, and exempt from disease. The temperature is very even, varying during summer seldom more than from 75° to 80° of Fahrenheit, nor in winter more than from 45° to 30°. Snow during the two winters, little as there was of it, never remained forty-eight hours on the ground.

The forest, so far from being dense, seldom contains more timber, after cutting out the smaller growth, as dogwood, &c., than is desirable for woodland pasture. The rocks, as far as my rambles have extended, are "few and

---

* See a table of population, by an annual increment of three per cent., in Niles's Register, January 11, 1845, page 300.

far between." The better spots of soil (and there are enough to provide every farm with sufficient remunerating arable land, under a provident and enlightened system of tillage) are covered with nutritious weeds, as pea-vine, &c., &c., which are nearly all greedily devoured by sheep and cattle, and on which they fare well. The poorer soil is covered with sedge-grass, which my sheep have invariably eaten with avidity.

When our herds and blue-grass lands, which we are laying down, will be fit for pasturing, the cost of wintering will be greatly reduced, as the former yields good grazing in February—the latter during the whole winter. Our young cattle kept in good condition on the winter range and two ears of corn per head per day.

Although the wolves of our mountains are larger than those of the prairies, and may be more difficult to exterminate entirely, yet, thanks to our good hunters, their ranks have been already so thinned that they mostly prowl about alone, or at most in pairs, committing their depredations by night, on the sheep and hogs that are left to shift for themselves. In the two years that I have been here, I know of but two instances of their having attacked young stray cattle by night. By day, sheep are perfectly safe; and I should presume that every good sheep-master would have his flocks, for inspection, home at night, when any common fence will be an ample safeguard for them.

C. F. KRAMER.

WOOLVERLY FARM, MARION CO., TENN, *June* 24.

MR. FLEISCHMANN'S ACCOUNT OF WOOL IN GERMANY.

VIENNA, *December* 1, 1845.

DEAR SIR: In a former letter I stated that I was present at the convention of German agriculturists which was held at Breslau in the beginning of September last. Being held at the capital of Prussian Silesia, a country famous for the production of the finest Merino wool, the subject of wool was rendered particularly interesting, on account of a large collection of fleeces and specimens of the best breed of Electoral rams and ewes being exhibited to the inspection of the members.

The wool-growers of the neighborhood of Breslau, and other places of Prussian and Austrian Silesia, Bohemia, Moravia, Hungaria, Russia, Mecklenburg, and Saxony, sent several fleeces of their finest animals, for the purpose of showing the progress the above-named countries are making in the improvement of their flocks. One of the largest halls of the university, where the meetings were held, was used for the exhibition of these fleeces. They were spread out upon tables provided with printed labels, which gave the age and sex of the animal, the weight of the fleece, the stock from which they sprung, with the name of the proprietor, and country where they were sent from, in order to facilitate, by comparison, the examination of those interested in this branch of husbandry.

These fleeces were the best which the above-named countries could produce; and it was a rich treat to the connoisseur of wool to see the state and progress of that branch of industry in so many countries. They all differed in degree of fineness, and more or less in the requisite character to

be pronounced perfect. Only two of them were considered as bearing all the signs of a perfect Electoral wool.

They were all of a high degree of fineness, but wanting in a "constant character," as the Silesian wool-growers call it, or in weight, in the length of the wool-hair, and in many of those demands which are made on a fleece of "constant and thorough character."

Those which were pronounced as answering all the qualities of Electoral wool came from Prussian Silesia. This province has gained the reputation of producing not only the finest wool, but to be the only market where thorough blood can be obtained, and to which wool-growers come from near and abroad to select and buy stock to improve their flocks. Saxony has lost its former fame, which arises from mismanagement, and from the increase of population, in consequence of which land becomes too valuable to be used for pasture.

The high degree of fineness to which wool has been brought by the most renowned wool-growers of Silesia, can only be fully appreciated when wool from the present period is compared with that of the years when the first Merinoes were introduced into Germany; which proves to Spain that it was not the climate, nor the rich and suitable pastures, but perseverance, and, above all, intelligence, which took from them the golden fleece.

Nature has done something for this province: its lands are high and dry; the pasture has been improved by its high cultivation; the climate is neither too cold nor too warm, so that a thick cover at any period of the year is inconvenient to the animal. The population of this portion of Germany is known for its superior degree of intelligence; which, when added to the common virtues of the Teutonic character, industry and perseverance, gives them the advantage over other countries.

Kuchelan, Hennersdorf, Gross Sterlitz, Chrzelitz, are the names of the places where the finest stock is raised, and to these places rush the wool-growers of other countries from great distances, at the beginning of every year, when the surplus stock is sold, to obtain a few heads of these famous breeds.

The prices for which some of these rams are sold seem enormous, and it will astonish some of our American farmers when they are told that a single ram is sold at from $1,500 to $2,000, and then the buyer considers it a favor to have obtained such a famous animal. The rich estate-holders of Russia, Hungary, &c., &c., seem to pride themselves on having it said that they obtained a certain famous ram for a great sum of money. It is here as it is everywhere, sometimes—more for the name than for the intrinsic value of the object; and a ram from another place, for one fourth of the price, would answer the purpose just as well.

The flocks of Prince Lichnowsky have the reputation of being the finest, and of most thorough blood; as, for forty years, he has never relinquished for a moment improving his flocks. He has in Prussian Silesia about 8,000 head, from which he sells every year the surplus number for the sum of 40,000 rix dollars; and it is he who obtains such high prices for single heads.

Experience has shown that only thorough blood should be employed in the improvement of stocks of all description, and the wool-grower is very desirous to obtain it from a flock of established character, where the wool has all those requisites which the manufacturer requires of Electoral wool. Sometimes inferior flocks produce animals having all the requisites desired;

but such an animal will produce lambs inferior to itself, and full of the faults of the parents. Such mistakes, which arise from want of knowledge or misapplied economy in the purchase of stock to breed from, will retard a flock for years, and produces faults which are deteriorating to the whole character of the wool.

The selection of stock to breed from requires a well-practised eye, to detect the injurious character of the wool upon the different parts of the sheep, and at the same time to select an animal which has the proper shape and strength to suit his flocks, the climate, and the local conditions.

Several attempts have been made in the United States to raise fine wool, which could bring prices equal to those of the Silesian market; but it never succeeded fully. The first importation of Merinoes from Saxony was at an early period, when Saxony flocks had no constant character in their wool—when a fine and faultless animal was scarcely to be got; and at that period the wool-growers of Saxony had, neither, the experience to give advice to others. Those imported from Spain were of as coarse a nature as those of Saxony, and the whole business of crossing was not conducted with sufficient care. The importations made of late are of a higher degreee of fineness; but, as it is generally a matter of speculation on the part of those to whom the well-meaning wool-growers intrust the business of selecting and buying, the selections are made from flocks of less thorough blood and imperfect character of wool, and the name of being Saxon or Silesian sheep must generally cover all the faults of the chosen stock.

Those who know the country, the language, and are good connoisseurs, are made the dupes of the cunning speculator. How easily, then, is it to deceive a stranger, from a foreign country, whose time is limited, and who has to trust to that which is told him.

Nature has destined that the United States shall be the granary of the world, and that its extensive tracts of mountainous land shall raise the necessary material for clothing for its vast territories. The high Alleghany will give to innumerable flocks of Merinoes an excellent pasture during the hot days of summer; and, when the snow covers the mountains, the spreading plains below the snowy summit will, nearly all the year round, yield sufficient pasture, especially in the more southern parts of the Union, where scarcely a handful of fodder will be required to be laid in for winter. The luxuriant heavy grass of the prairies will answer for the English long-wooled sheep, and for the hardy zackel of Hungary, which furnishes also the most delicious mutton.

I obtained, from the committee which was appointed for this branch, specimens from the different fleeces; and I flatter myself to be able to lay before you a collection of specimens rare and curious.

I prolonged my stay in this part of Germany to obtain wool from the animal before it was shorn and washed, and shall visit for that purpose, yet, the most celebrated establishments of that kind.

I made drawings of those rams and ewes which are considered as having the true character of Electoral breed, and hope to add some more such *sheepish* likenesses from the stock of the most celebrated flocks.

I made also a collection of sketches of agricultural implements of the different countries I traversed, which, I think, will interest you, not only for their originality, but as a proof how a nation clings to the agricultural implements as well as customs of their forefathers, whereby we are enabled to trace the different races, in the most distant ramifications, with

certainty; and sometimes, when no trace has been left of their original language, the plough tells us from where they come. The plough is also the scale by which we can judge of a nation in regard to its intellectuality and general state of social condition. We may fairly say, as is the plough so is the intellect, and so is their personal liberty.

The United States proves fully this position: *there* it is that we find the best improved plough; there is it, also, where the farmer stands the highest in point of intellect and personal freedom, over all others of the globe.

The farmer of the United States endeavors also to enrich himself with the knowledge of his noble profession. I hope the day is not far when they will take measures in order to accomplish this important object more fully; that they will instruct their representatives, in State legislatures, to establish regular agricultural schools, in which their sons, after having passed through the ordinary schools, may receive at that school that information which enables them to husband their lands with more advantage, according to the rules deduced from experience; whereby the country will be enriched, love to the land of their fathers increased, and the main pillar of the republic strengthened.

In my next I shall say a few words on agricultural schools. I visited, among others, that of Moegelin, near Berlin, (Prussia's first establishment of that description,) which was intrusted to the wise direction of Thaer, a name so well known to the agriculturist of all countries.

Your most obedient servant,

CH. L. FLEISCHMANN.

Hon. EDMUND BURKE,
Commissioner of Patents.

From Willmer & Smith's European Times of January 4, 1846.

LIVERPOOL ANNUAL WOOL REPORT.

The favorable views we expressed in our last annual circular of the prospects of the wool trade were fully realized during the first six months of 1845. An extent of consumption, probably without precedent in the same period of time, was accompanied by an unusual steadiness of price, and freedom from any appearance of speculation or over-trading; and yet there has seldom been a period, with the elements of the trade so sound and promising, that has resulted in so little profit to those engaged, whether importer, stapler, or manufacturer. This we principally attribute to the relatively high price of the raw material.

The early months of the year were marked by unusual activity. The protracted winter gave an extension to the home trade, whilst the continental demand, particularly from Germany, was good. Some inconvenience was experienced by the export houses from the navigation continuing closed to so late a period. In many cases goods ordered arrived too late for the Leipsic Easter fair, which may, to some extent, interfere with future orders. In June and July it was felt that the continued prosperity of the wool trade would much depend on the result of the approaching harvest. The general feeling being favorable, imparted confidence to transactions, and led to an improvement in the value of most descriptions of

wool. These anticipations having, unfortunately, not been realized, the wheat crop being reported as deficient in quantity and inferior in quality, with the admitted failure of the potato crop to a serious extent, have, for the last few months, subjected the trade to feverish excitement, and much limited the amount of business; other causes have contributed to this result. The large absorption of trading capital in railway and other schemes; the consequent increased value of money and restricted banking accommodation; and, more than all, the narrowed consuming power, arising from the large advance in the cost of subsistence to the great bulk of the population, have operated injuriously on the trade during that period. Notwithstanding these obstructions, we report a less depreciation in value than might have been expected. Stocks of goods are generally light, and of the raw material by no means excessive. We must not omit to notice the intense anxiety with which every section of the trade is awaiting the expected legislative action on the corn laws. Should it terminate in the total abandonment of all import duties on corn and provisions, the change will be of incalculable advantage to the wool trade at large; and we believe that no branch of it will reap more substantial benefit than the home wool-growers.

The growing importance of this place as a wool market is becoming more apparent every year, as shown by the rapidly increasing imports; and, from its contiguity to the manufacturing districts of Yorkshire, Wales, and Scotland, it will, no doubt, before long, command a much larger share of the trade. Our receipts from Australia have hitherto been comparatively insignificant, London continuing to take by far the greatest portion of colonial wool. We are surprised at this, when the many advantages of this port are considered. Its vicinity to numerous consuming districts is certain to insure a large attendance of the smaller manufacturers, who form the chief support of the public sales. In London, the excessive quantities brought forward at one series (sometimes exceeding 30,000 bales) unduly limits the time for examination; operates, even under favorable circumstances, against prices, and, in dull times, is disastrous in tendency. We are convinced that, if a more equal distribution of imports were established, the return to merchants would be more satisfactory.

Australian.—The total receipts from these colonies show a steady increase, which will be much extended by the enhanced value of sheep, having put a stop to the boiling down for tallow. The condition of the last clip has been generally satisfactory. By shearing earlier, the burr was partially avoided, and the season seems to have been favorable for washing. Previously to the first arrivals, which were much earlier than usual, the stocks at home were nearly exhausted. The accounts from the German fairs stated an unusual demand for low and middling qualities for their own consumption, while the French were known to be operating largely in Spain. These circumstances caused the first public sales to go off with great spirit. In October trade began to slacken, though the result of the public sales in London during that month was quite as favorable as could be expected. The large arrivals up to this date (which were, in fact, larger than apparent, owing to the increased size of the bags) induced the wealthy dealer and consumer to stock freely, under the impression, which we think well founded, that the entire import will be required before next season. We are glad to notice throughout the year an improved demand for the better qualities, which will be encouraging to the growers who attend to their flocks. Combing wools have been little in request, owing to the

depression of the worsted trade. This branch is beginning to rally, and promises a better demand in the spring.

Cape of Good Hope.—The shipments from this quarter show great improvement, amply testified by the high rates the best flocks have commanded during the season. This result of judicious management in selection and careful packing will, we feel assured, be sufficient encouragement to perseverance. It is only by such means that former prejudices can be overcome. The best parcels now take equal rank with those from Australia, and are purchased by the trade with full confidence, whilst the more mixed and inferior kinds are an article of doubtful sale. The system of packing unwashed and yolky fleeces with the washed is most prejudicial, and cannot be too strongly pointed out.

Spanish.—Our market has not kept pace with the advanced rates paid for this description on the other side, occasioned by French competition. It has, therefore, been difficult to effect sales at remunerating prices to the importer. The demand of late has been chiefly confined to middle qualities.

Portugal.—Best R.'s have been readily saleable. Most other kinds have been little sought after.

Oporto Mountain.—The demand has been chiefly confined to the best combing parcels; other kinds have been comparatively neglected.

United States.—The import from this quarter affords a striking proof of the beneficial effect of the remission of the wool duty. It has excited great interest and surprise in the trade, and may be considered the greatest novelty of the year. The quantity received to this period, as an experiment, exceeds 3,800 bales, comprising a great variety of qualities. It is to be regretted that the unfavorable turn of trade has been against the operation. In washing and preparing the wools sufficient pains have not been taken; and there is a want of discrimination in the selection of qualities. So far as used they have been highly approved; and we have full confidence that, if got up with care, they would be highly esteemed in this country. The American prairies afford peculiar advantages for the growth of wool; and we believe this branch of the trade will become one of great and increasing importance.

Peruvian and alpaca.—Till within the last few months, the supply of sheep's wool was limited. It is now increased, but the demand is restricted at rather declining prices of late. The imports of alpaca have been rather large. There are no means of ascertaining the exact quantity, but a careful investigation leads us to estimate it at about 18,000 ballots at 80 lbs. each. It must be borne in mind that, during 1844, great difficulties attended the shipment; and the apparent excess of 1845 represents a portion of the previous year's clip. For the first six months there was great activity, and consumers bought freely for arrival. The demand has since been heavy, at almost nominal prices. The high rates abroad render it probable that considerable loss will attend the import.

Buenos Ayres, &c.—Good clean parcels have been in fair request. All other kinds have been rather heavy of sale, and at declining prices, in consequence of the expense and difficulty in getting them cleaned. The unsettled state of the trade on the other side will no doubt interfere with shipment, and may cause an improved demand.

East India.—Under this head we notice a considerable increase, and it is satisfactory to observe that the demand has fully kept pace with it. More

attention has been paid to the assortment, which it is desirable should be persevered in. The increasing demand for low wools will enable the trade to take any quantity that can be furnished.

Russia.—Here the increase appears considerable; but the imports have arrived much earlier than usual. The trade generally has been heavy, except for good combing parcels, which have throughout commanded full prices. The greater portion has been of an inferior description.

Mediterranean.—The items under this head, including Italian, Greek, Smyrna, and the varieties of Turkey wools, have been dull of sale at prices unremunerating to the importer. Some quantity of Egyptian wool has been received, a description which has not before found its way to this country. It is clean and well washed, and a portion is well adapted for combing, but there is a great deal of short mixed with it. Greater care is required in the assortment. The decline in English skin wools has affected its value. We doubt if it will answer except when English combing wools rule high.

English, Scotch, and Irish.—Notwithstanding the depression in the worsted trade, the consumption has reached a full average. Prices have varied little throughout the year, the general range not varying to any material extent from this period last year. Stocks with staplers and manufacturers are light, and not extensive with the farmers, who show more disposition to hold than give way at present.

In exports, the principal feature is the increased amount of woolens sent to the east, which, we understand, form one of the most lucrative branches of the trade with China, the rising importance of which it is difficult to estimate. The exports of woolens to the United States, which have, for some years past, been diminishing, continue to recede; but the tone of the President's message on commercial affairs leads to the expectation that this important market may again revive.

HUGHES & RONALD.

Liverpool, *January* 1, 1846.

From the Liverpool Times, January 1.

APPENDIX No. 27.

HOGS—THEIR PRODUCTS, &c.

From the Cincinnati Chronicle.

PRODUCTION AND TRADE OF HOGS IN EUROPE AND AMERICA.

The immense production of hogs in the United States, and the heavy trade in them at Cincinnati, demand something more than a mere superficial view of the transactions, at one point, in order to understand the magnitude and relations of the trade. We can furnish the commercial reader with some statistical facts, which will serve as landmarks in taking a broad view of the subject.

In the year 1839 there were in the United States, in all, 26,301,293 hogs. Of this number more than one-half of the whole were in eight States, viz:

Tennessee had	2,926,607
Kentucky	2,310.533
Ohio	2,099,746
Indiana	1,623,608
Illinois	1,494,254
Missouri	1,271,161
Mississippi	1,001,201
Alabama	1,423,873
Total	14,151,983

The States of Virginia, New York, and North Carolina, each, have more hogs than Illinois and Missouri; but we have taken the States of the west and the southwest together to show the result.

Now we want to draw two or three inferences from the number of hogs in the several States, before we compare the production with that of Europe.

1. In the first place, hogs are fatted and nearly supported on maize and Indian corn. They exist, therefore, in the several States, just in proportion to the production of Indian corn. Now, Tennessee has the most, and the three States of Tennessee, Ohio, and Kentucky far more than any other three States, of both Indian corn and hogs. The twenty-six millions of hogs in the United States can scarcely consume less than two hundred millions of bushels of corn! They are, therefore, the greatest market for that article.

2. If we suppose these hogs to average 180 pounds each, and to be worth (as they are) $3 50 per cwt., then this animal alone is, in the United States, worth ONE HUNDRED AND SIXTY-SIX MILLIONS OF DOLLARS, or three times the entire cotton crop for the year 1845. The value of swine in the State of Ohio alone exceeds twelve millions of dollars.

3. It is important to discover how large a proportion of swine is annually killed. There are two sorts of consumption for swine: one may be called the *commercial*, and the other the *domestic* consumption. One is

for family use, and the other for commerce. Almost every farmer's family kill one or more hogs. This is a constant drain on the increase. But, on the other hand, the increase of swine is so great that it will exceed, in one year, the original stock, unless checked. The main inquiry is, how large a proportion of hogs are fatted in order to supply the *provisions* of commerce? In the year 1845 there will have been killed at the various pork packing establishments of Ohio about 500,000 hogs. About 150,000 of these may be set down as from other States. It is fair, therefore, to assume that commerce consumes about 350,000 hogs in Ohio per annum. The present stock cannot be much, if any, under 2,500,000. It follows, therefore, that commerce consumes near about one-sixth part of the stock on hand. We believe that, in the United States generally, this is much too high an estimate; yet the figures, in the western States, will show this result very nearly.

4. But suppose the total is really as great as the facts imply; then it follows (a fact of great moment to the packer) that *no safe conclusion whatever can be drawn from the number of hogs killed in one year, of the real number of the stock that will be brought to market next year.* This is obvious, if the reader will reflect that a given stock of hogs will nearly double themselves in one year, and that yet the number of hogs of commerce is only one-sixth part of the original number! This is the great source of the constant errors made in calculating the number of hogs to be brought to market, and the effects on the market. The truth is, the domestic or family consumption is the great fact, and *that* we cannot arrive at exactly.

We shall proceed to show the number of hogs raised *proportionably* in Europe and America. We have before us McGregor's Statistics, which contains a table of the agriculture and live stock of Europe for 1828. Since then the population of Europe has increased more than ten per cent.; and if we add ten per cent. to the live stock, we shall have the full amount, for this species of stock does not increase in densely populated countries equally with that of other productions.

	Swine of Europe.
Russia	16,380,000
Austria	6,050,000
Great Britain	5,775,000
France	4,950,000
Italian States	2,750,000
Bavaria	1,650,000
Netherlands	1,540,000
Prussia	1,645,160
Sweden	1,320,000
Spain	1,100,000
Portugal	770,000
All other States	2,348,000
Total	46,278,160

To one who is acquainted with the abundance of swine, and the facility for raising them, in the United States, this table must seem extraordinary. It shows that Russia, Austria, and Great Britain, having a population of *one hundred and twenty millions* of people, have only as many swine as the United States, with *twenty millions!*

Eight western States, with a population of *six millions*, have as many swine as great Britain, France, Prussia, and Bavaria, with *seventy-five millions! The European States have not enough Indian corn to feed them upon.*

The proportion of swine between the United States and some of the European States is thus:

United States	to Prussia	6 to 1
" "	to Austria	9 to 1
" "	to Great Britain	7 to 1
" "	to France	10 to 1
" "	to Spain	16 to 1

Russia being a thinly populated country, and having the most *mast*, has the most swine; but, for the converse reason, the southern States of Europe have the least. The United States have six times as many, in proportion, as Russia.

The same disproportion extends, but in less proportion, to other animals. If the people of Europe were a meat-eating people, they could not find a supply in their country. These animals would be killed off in half a dozen years. But they are not a meat-eating people. They live upon every species of vegetable, much as the animals do.

In Ireland they depend upon potatoes: in Scotland, in no small degree, upon oatmeal. Strange as it may seem, thousands of people in Spain and France live, in a great degree, on chestnuts—a food which is scarcely fit for pigs to eat. In some countries they eat rye; and in Russia they mix all the *bran* of grain, making a very coarse, rough bread.

The pork of the western country is chiefly in demand at the Atlantic seaports, for our commercial marine, now rapidly approaching the largest in the world. The adventurous whaleman, the hardy fisher for cod and mackerel, the thousand coasters, who sail in every bay and inlet from the Penobscot to the Rio Grande, all, more or less, eat pork. It serves both as butter and meat, with the fish and potatoes which they have constantly on hand.

The demand for American pork is, on the whole, likely to increase; because the class of people who eat it are increasing, and there is no other country to supply the demand.

From the Cincinnati Chronicle.

BONES, WHIP HANDLES, IVORY-BLACK, HOOFS, PRUSSIAN BLUE, OFFAL, &c.

This is a motley heading, but is exactly adapted to what we have to say. A few days since we took a ramble up Deer creek.

* * * * * * * * *

The creek shore, above Ninth street, is measurably lined, and in one instance, we believe, covered by slaughter-houses—some devoted to disposing of hogs, and others of cattle—tanneries, bone-mill, grease-trying establishments, and similar odoriferous vocations; and in the winter season the stream should be known as bloody run, for such it literally is, its

color being nearly scarlet. A brewery adds its mite, as well as a steam lard and tallow manufactory; to the general aggregate of which the creek is the depository.

But, however undesirable is the brink of this murmuring stream, the vale through which it runs is nevertheless a fountain of wealth. Among the establishments there is one which is a common receiver of nearly all the offal of the city slaughter-houses. From it is turned out an immense amount of grease and inferior lard. A large portion of the daily market beef-legs and shanks is purchased by the proprietor; and, after the marrow and grease are extracted, the bones are sold for the various purposes of button-making, whip handle finishing, the manufacture of China-ware or porcelain, and also ivory-black. Of the latter, large quantities are used in the manufacture of shoe blacking; and a mill in this noted vale is expressly appropriated to the grinding of bone, pith of horns, &c., for the manufacture of black.

Of the small bone used for black and porcelain, this house ships to foreign ports, mostly Europe, about 400,000 pounds per year; and of the large bone, which are principally used for the ferules and butts of whip stocks, and the manufacture of buttons, about 130,000 pieces. These quantities are exclusive of the amount consumed here, which is very considerable, particularly of the former kind. A few years ago, nothing of the kind was done here, and, as far as bone was concerned, was entirely a waste. The prices here are, for the small, $16 per ton, (a large contract closes with 1844, for export to Europe, at that rate, packages included,) and for the latter, $10 per 1,000 pieces. The price last year was $8.

Soap-grease is the great staple of this Vesuvius, very large quantities of which are shipped to the eastern cities. Forty thousand dollars' worth was mentioned to us as the value of what is at this time on sale in New York alone. The prices here now are, four cents for No. 1, and three and a half for No. 2.

One of the other articles made to a great extent is neat's-foot oil, from the nether legs and hoofs. This sells, by wholesale, at 62 to 75 cents per gallon.

Another is sausage skins, with which not only our own market is supplied, but shipments are contantly making to the south and east. They sell here at $10 per keg—size, the common lard keg.

Hog's bristles are another thing prepared by this and other houses, or house in the city; and of this article large shipments are also made, both of the combed and tied, used by saddlers, shoemakers, &c., and of the curled. The former kind sells at 30 to 35 cents per pound. The curled are used for the same purposes to which curled hair is applied—mattresses, cushioned chairs, sofas, &c.

One other thing we learned in this our evening ramble, was, that we have with us a manufactory of Prussian blue. The stock from which it is made is cattles' hoofs and plucks, and the blood of hogs and cattle. The hoofs command $16 per ton. The manufacturer is a German. It is but a year or eighteen months since he commenced operations, and cannot be said to be fairly under way, but has sufficiently tested the experiment clearly to demonstrate the practicability of successfully competing with the foreign article, both as to quality and price, and he expects in a few years to be able to consume a very large portion of the blood to be obtained here. We were also told of an instance of a foreign demand for blood. The facts

we have stated are a few instances of the economy with which science is capable of making us acquainted, and of the value of the skill by which it can be effected. Shall we cultivate the arts and sciences, and encourage skill and enterprise in our country?

From the Popular Record of Modern Science.

THE VALUE OF A DEAD HORSE IN PARIS.

The use to which dead horses are put may be gathered from a brief account of the establishment at Montfaucon, near Paris, consisting of what we should call knackers' yards. After the horses are deposited there, the hair of the mane and tail is cut off, which amounts to about a quarter of a pound; the skin is then taken away, which is disposed of to the tanners, and used for various purposes. The shoes are sold as old iron; the feet are cut off, dried, and beaten, in order to make the hoofs come away, or are left to putrefy till they separate of themselves, when they are sold to turners, comb makers, manufacturers of ammonia and Prussian blue. Every morsel of fat is picked out, collected and melted, and is used for burning by makers of enamel and glass toys, greasing shoe-leather and harness, and manufacturing soap and gas. The workmen choose the best pieces of the flesh to eat, preferring those about the head, and sell the rest for dogs, cats, hogs, and poultry. It is also much used for manure and making Prussian blue. The bones are disposed of to cutlers, fan makers, &c., and are often made into ivory-black; and also occasionally serve as fuel for melting the fat, and for manure. The sinews and tendons are sold to the glue makers; the small intestines are made into coarse strings for lathes, &c., or serve as manure. Even the maggots, which breed in great quantities in these yards, turn to account, for many are sold to the fisherman; and the rest, when developed into flies, attract such numbers of swallows, that the Parisians make a shooting ground of the neighborhood.

PORK PACKING AT CINCINNATI.

The books of the several slaughtering-houses in Cincinnati show the following number of hogs packed during the past season at that place. The statement is no doubt correct:

Cincinnati—J. W. Coleman & Co.,	4 houses	130,959
John Jaquess,	2 "	48,403
Pugh & Co.	1 house	38,384
J. C. Hughes & Co.	1 "	34,502
Total		252,246
Covington—Ashbrook & Hughes,	1 house	12,736
Estimate for wagon, railroad, and river receipts		22,500
Making the total number packed at this point		287,482

The following account of the number of hogs packed at this city each season for the last fourteen years, and also the price per hundred pounds at which the market opened each year, may be useful as a future reference:

Year.	Number.	Price.
1832-33	85,000	
1833-34	123,000	
1834-35	162,000	
1835-36	123,000	\$1 00 a \$6 25
1836-37	103,000	6 00 a 7 00
1837-38	182,000	3 50 a 4 00
1838-39	199,000	5 50 a 6 00
1839-40	95,000	3 00 a 3 50
1840-41	160,000	3 50 a 3 75
1841-42	220,000	2 00 a 2 50
1842-43	250,000	1 62 a 2 00
1843-44	240,000	2 25 a 2 65
1844-45	213,000	2 50 a 2 70
1845-46	287,000	4 00

APPENDIX No. 28.

POULTRY—FEEDING CHICKENS—PROFITS OF POULTRY.

From the London Gardeners' Chronicle.

POULTRY.

The economy of poultry may be classed under three heads: first, in their natural state, which is the department of the naturalist; second, in their domestic state in the country, with a full range of the farm-yard and fields, in which the poultry-keeper is concerned, for his profit; and, third, in their artificial state, in or near towns, in pens or yards, which will chiefly engage my attention in the present article. The best and cheapest method of feeding I must leave to be detailed by those who keep poultry in large quantities.

Shelter.—Fowls should always be kept in a dry, warm, sheltered situation, (a southerly aspect is to be preferred,) for they enjoy and benefit greatly by the "warms in the sun," as well as requiring protection from its scorching rays, and a secure (storm) shed for rainy weather. The roosting-house and laying-house, if separate, should communicate, that early layers may have early access to the nests, and also communicate with the storm-shed, for the fowls to run in in security, if they should leave their roosts early in the morning. The nests should be numerous, either in boxes or baskets—not too deep, but roomy; some situated high, some low, and as independent of each other as possible; each supplied with sweet, short, and soft straw, and a small nest-egg or two of chalk, the size of a pigeon's egg. If the nests be too deep, they break the eggs in jumping in and out; and if the nests are not roomy, sitting hens have no room to turn easily, and consequently break the eggs by not being able to get to them softly. They then eat the broken eggs, which gives them the habit of doing so at other times. They should roost warm at night; the perches high from the ground, and of easy access, by means of lower ones or ladders. The more lightsome the house, the better for promoting dry air and a free circulation; besides, fowls cannot see at all, being quite stupefied and helpless, in the dark; consequently the feathered tribe always retire to roost before the sun goes down. Shutters to the glazed windows are unnecessary, except for better security, or to prevent fowls from leaving their roosts too early in the morning, to disturb ticklish neighbors; otherwise they come out almost as soon as daylight begins to appear. The feeding places, if under cover, so much the better, as a precaution for wet weather, and as far as possible removed from the nests, that the hens which happen to be laying at the time, or which may be sitting, may not be disturbed and enticed off their nests and eggs at improper times. Being evidently natives of a warm country, they are scarcely yet perfectly acclimated in our variable and colder regions; although so widely diffused, from time immemorial, over the whole face of the globe, they have retained a peculiar susceptibility of damp and chillness—most of their diseases arising from rheum or catarrh—catching colds. The lungs of fowls are particularly tender: the finer the species, the less is it hardy.

Cleanliness.—Fowls, being cleanly by nature, thrive when regularly attended, but degenerate and sicken if neglected. In an artificial state of ex-

istence they require to be supplied by art with what, in nature, they would obtain for themselves. For this purpose they should have a regular supply, in some convenient part of their shed, of sifted cinders daily, to roll in and cleanse themselves, and which should be often changed. This precaution will keep them entirely free from vermin of any description.

Green food.—This being quite as necessary for health as corn, to supply this requirement of nature they should have daily a good supply of sweet and fresh green vegetables. Cabbage and lettuce are the best, (turnip-tops and watercresses,) but on no account any sour plants, which scour them, (as do spinach, the cuttings from grass-plats, and most sorts of garden-seeds,) as their instinct does not serve them to choose the wholesome from the noxious weeds, more than it does animals that happen to stray into a clover-field, or happen to receive too large a quantity into their stables. I have known them to burst. Green food, with fowls, is an astringent—the very reverse from what vegetables are with us. This fact will not appear so surprising when it is recollected that one takes them raw, and the other cooked.

A plentiful supply of clean water daily, in well-cleansed vessels, and wholesome food, is necessary. Frequent changes, and mixtures of corn, improve the appetite. Barley is decidedly their staple food in this country; Indian corn, or sometimes rice, mixed, for a change. Oats occasionally; but, in too large quantity, are apt to scour. Occasionally buckwheat and hemp-seed, as a stimulant, mixed with the barley for a change, are very beneficial, particularly whilst moulting. One meal may be composed of boiled or steamed potatoes, well mashed up whilst hot, with a portion of barleymeal or oatmeal for a change, but which must be allowed to remain till cold. Books, copying errors from one another, make a great mistake in advising food to be given hot. It is unnatural: they have no good cooks amongst them in their own state; and it is decidedly injurious to their digestive organs, except when fattening, when they are doomed soon to be killed for table. Feed twice a day at least, or three times, if not to fattening; morning, early, before the usual hour for laying, if possible; at noon, (the noontide meal may be the potatoes, as above directed,) and before sunset, (not later than four o'clock,) that they may go to roost by daylight, or they will go without their food. Regularity greatly tends to health, and disturbance of any sort is very hurtful. Rice occasionally, boiled in a cloth, greatly increases its bulk, and they are very fond of it. Reaumur says that great economy is derived from steeping or boiling the barley, to increase its bulk, when they will be satisfied with one-third less quantity. But I cannot speak of this from my own experience, nor can I say that beneficial effects are produced by giving them much flesh, raw or boiled. But fat, as advised in books, produces scourings; spiced or salted meats, and kitchen stuffs, are certainly pernicious to their stomachs. In fattening for the table, when they are not required to live long, or show fine feather, this may not be of any consequence. Will some of your practical correspondents enlighten us? They require in pens or small yards, in towns, to be well supplied with grit, sand, and small gravel; slacked lime, and old mortar pounded, is very beneficial, and serviceable in assisting to make the pen or yard dry. I will add to the above, that there is no economy in keeping poultry in towns in small quantities, which is always exceedingly expensive, if well fed and taken care of; which, however, is compensated for to those who wish to make certain that the eggs are quite fresh and newly laid. All calcula-

tions of expense must be erroneous, there being so many contingent expenses. As a source of trade, much depends upon rearing the best breeds, to be early in the season, laying in stock and store at proper times, having a ready sale for produce, and to "buy cheap and sell dear."

KEEPING POULTRY—PROFITABLE BUSINESS.

A correspondent, living on a ten-acre lot near Port Richmond, Staten island, has sent the New York Sun the following copy of an account with his poultry-yard for the year 1845, viz:

Seventy-one hens—Dr.

To grain	$7 00
To repairs of coop	1 25
To pieces of meat and charcoal during the year	3 10
To profit and loss	93 65
	$105 00

Cr.

By 11,640 eggs	$65 00
By 270 chickens	40 00
	$105 00

The male birds, numbering six, are of course not counted as "hens," although the expense of keeping them is included in the items on the Dr. side of the above. He had on hand at the end of the year 58 chickens, 71 hens, and 6 cocks, valued in all at $24—the amount he entered them at in his stock account. The profits of the year, amounting to $93 65, form a respectable item in domestic economy. Why may not our citizens improve on this example? A coop will occupy but a small space in a yard, and poultry and fresh eggs are generally high in the Baltimore market.

Baltimore Sun.

From the Agricultural Almanac.

PROFIT OF HENS.

It is frequently asserted that poultry is more plague than profit. But this, like many other assertions, must be taken with proper qualifications. We contend, if you have a good breed of fowls, take proper care of them, and are near a reasonably good market, that the keeping of fowls is as profitable a business, for the amount of capital invested in it, as a farmer's boy or the women of the family can be engaged in. To prove this, we will cite one example. When we were at the pleasant farm (last September) of Messrs. H. and J. Carpenter, of Poughkeepsie, their brother, Mr. Gerard Carpenter, showed us an account of the number of eggs laid by their hens up to that time from the 1st of January. It was so exact and satisfactory, that we requested him to continue it to the end of the year; which he has obligingly done, and now here is the result.

He commenced, on the 1st of January, 1844, with 67 hens and 3 cocks. Out of this flock were sold and lost, by the 1st of May, 7 hens; from that time up to the 16th of September, they lost two more. Since then we are not informed what the losses have been. It would probably be fair to set down the average stock of hens during the year at 60 head. These laid in the following months, all of which were consumed by the family or sold—

In January	191	eggs.
February	400	"
March	892	"
April	1,037	"
May	1,086	"
June	700	"
July	838	"
August	740	"
September	540	"
October	113	"
November	21	"
December	none.	
	6,558	"

In addition to this number, it is supposed full 300 were used for sitting, got lost, broken, or spoiled, which are not taken into the above account. The average price that the eggs brought at Poughkeepsie was $1 per hundred, which makes their value - - - - - - $65 58
Chickens raised, 101—at 20 cents each - - - - 20 20

$85 78

We suppose that this flock of hens may have consumed grain during the year equivalent to 70 bushels of corn. This is allowing three-fourths of a gill per day throughout the year to the flock of hens, and nothing to rear the chickens; but as, during the summer, hens that have the range of a farm need no feeding, this quantity of grain is considered ample for their support.

At 50 cents per bushel for the corn, this would make the expense of their feed $35, which, deducted from the value of eggs and chickens, leaves a net profit of $50 78. It is considered that the manure of the hens, and the insects they destroy during the season, are equivalent to taking care of them.

The actual feed of the above hens was as much corn, mixed with a few oats, as they would eat; the grain being placed where they could always get at it. In the winter they had a little meat. They were not confined at all, and had access to lime and gravel while the ground was covered with snow. Their roosting-place was comfortably enclosed under the barn.

APPENDIX No. 29.

CULTIVATION.

From the Albany Cultivator.

An interesting experiment, showing at the same time the benefits of stirring the soil, and also the danger of drawing false conclusions, is given by L. Vernon Harcourt, in the agricultural department of the London Gardeners' Chronicle.

He had seen a statement that the tailings of wheat, called "chicken-scraps," being in fact only the refuse of the grain, would yet produce a good crop of the heaviest, fullest seed. Disbelieving it, and being desirous of undeceiving the farmers by proving its fallacy, he proceeded to try the experiment. Accordingly, a small plat of ground was sown, one-half with good wheat, and the other half with tailings. On returning home, after an absence of some weeks, in the spring, he was surprised to find the latter covering the ground as thick as the grass on the meadow; but found, upon inquiry, that the person having charge of the experiment, considering the seed good for nothing, had sown five or six times as much of it as of the other. As this thwarted the design of a comparison, half the thick sown was directed to be hoed out till of the same thickness as the other from good seed. The other half of the thick sown was left to take its chance. At harvest, the first twelve plants in one row of each sort were taken as a sample, and the produce weighed as follows:

	Grains.	Average ears per plant.
12 plants from good seed, weighed - -	926	6.6
12 plants from tailings, left thick, weighed -	351	3.8
12 plants of the same, thinned, weighed -	1133	7.8

It is of course evident to every intelligent person that the increase in the product of the hoed portion was owing to the cultivation by hoeing, which is further proved by the meagre supply from the unhoed wheat from the tailings. But the experiment performed under other circumstances, and with other seed, might have led to very erroneous conclusions.

ACCOUNT OF AN EXPERIMENT IN DEEP PLOUGHING.

BY REV. JOHN JAFFRAY, DUNBAR, EAST LOTHIAN.

The experiment was made upon a small field, which is sixty-five feet above the level of the sea. The soil is sandy, resting upon a sub soil of sand and gravel of great depth, and so thoroughly drained by the declivity of the surrounding lands, the want of moisture is its natural effect. There is but little difference between the soil and the stratum on which it rests beyond what culture and manure have made; but, from sinking of gravel, treading of horses, and pressure of the plough, year after year, and age after age, the sub soil had become crusted, hard, and beaten, as a road. In short,

from shallow ploughing, there was but little of cultivated earth ; and, as on all such soils in dry seasons, the crop was scorched aud scanty. With a view to render this field fruitful in any season, it was sub-soiled with the Deanston plough, eighteen inches deep, and sown with wheat for crop in 1837. The great vigor and luxuriance of the crop attracted general notice ; and it must have yielded an extraordinary increase, if it had not been lodged by wind and rain shortly after the ear appeared. Therefore it gave only thirty eight bushels of grain to the acre, but three tons of straw, which proved its great strength. To this crop, one of potatoes and two of wheat succeeded ; but it is the culture of this field for crop in 1841, and the result, which chiefly constitute this report.

It was all equally dressed with seaware ; and four acres of the same quality and description were measured and staked off. Two of these acres were ploughed twelve inches deep, with two horses, and two of them eighteen inches deep, with four horses. These two portions in all other respects were cultivated and managed exactly alike. They were planted with potatoes of the Don species in the last week of April, eight inches deep, twelve inches asunder, and in drills thirty inches wide, running at right-angles to the furrows of the experimental ploughing. The potatoes were planted deeper than usual, therefore the shoots were longer in coming through the ground ; but when they did appear, it was with great strength and regularity. They expanded their broad deep-green leaves, and grew vigorously in the dry sandy soil, in a very severe and long continued drought. It was soon evident that the deepest ploughed portion had the advantage. The stems and branches of its plants were stronger, and they first covered the ground.

The potatoes were lifted in the last week of October, when it was found that the land ploughed twelve inches deep produced fifty seven bolls per acre, and the land ploughed eighteen inches deep produced sixty-nine bolls per acre, being a difference of twelve bolls per imperial acre, of four cwt. to the boll.

* * * * * * * * *

The potatoes from the deep tillage were larger, more of one size, had fewer small ones, and not so many of a green color as those from the other division.

The quantity on the deep tillage is eighty-seven bolls per Scots acre, which is a good crop for any year ; and it will readily be granted that it is far above the average of the district this year, many fields not producing half a crop. * * * But though this is a greater crop for the season, it must have been still greater if the field had been less exposed, as it has no shelter ; and three days of very violent wind in the first week of August broke down the plants, which, from their great luxuriance, were then very tender, and checked their growth.

The practical conclusions to be drawn from this experiment are—

First, that deep ploughing increases the produce.

Next, that, as both portions of the land used in the experiment were opened up eighteen inches deep by the sub-soil plough for crop in 1837, the full benefit of that operation is not obtained till the earth so loosened is again ploughed up. And the reason is evident ; for it is then only that the soil is deepened, by an addition from the sub-soil with which it is intermixed, and rendered more fruitful.

Lastly : if deep ploughing increases the produce, it increases also the sup-

ply of vegetable manure; and a greater portion of manure, added to improved culture, must produce a progressive increase of fertility and of produce.

From the American Agriculturist.

BENEFIT OF SUB-SOIL PLOUGHING.

A farmer from Connecticut informs us that he has raised a field of corn the past summer which he thinks will average 80 bushels to the acre, and that he selected half an acre of the best, from which he gathered 134 bushels of ears, all sound and well filled out. That while his neighbors' corn adjoining was withering with the drought, his was luxuriant; and he attributes the whole of his success to sub soil ploughing. Another fact he stated was, that the whole expense of planting, cultivating, and harvesting, after the ground was ploughed, did not exceed $3 per acre; that he did not touch it with a hoe, but worked it with a harrow and cultivator; and what few weeds were not reached with these, about the hills, were pulled up by hand before going to seed. We intend to visit his farm next summer, when we shall have something further to report.

NEWCASTLE COUNTY AGRICULTURAL SOCIETY.

To the Committee on Farms:

Gentlemen: In competing for the valuable premium offered by the society for the best farm, taking into consideration the former and present condition of said farm, I proceed to give as correct a statement as my memory and a few notes taken from time to time will permit.

On the 4th of March, 1834, I removed to Wheatland, which I had purchased of J. A. Bayard, on a credit of ten years, in 1832. This part of the farm, which contained about 360 acres, is situated on Bohemia Manor, partly in St George's Hundred, Newcastle county, and partly (about 30 acres) in Cecil county, Maryland. It was very poor at that time, having always been rented from the first settlement of the country—which, by the grave-stone of the original proprietor, Agustine Herman, was in 1669—till the time of my purchase.

Wheatland, previous to my purchase, contained 524 acres, nearly all of which was tillable, there being no wood or other waste land upon the farm. It had always been worked upon the three-field system, one of which was planted with corn; wheat was then sown in the standing corn after the fodder had been gathered; then, after the wheat came off, the stubble was pastured one year, without having any clover or other grass seed sown. The next year it was again planted with corn, and so on with that impoverishing course; for which a fixed rent was demanded of 700 bushels of corn and 125 bushels of wheat. No oats were allowed to be sown. The 700 bushels of corn, at the present price of 40 cents per bushel, would amount to $280; the 125 bushels of wheat, at the present price, (90 cents,) would be $112 50—together, $392 50—and this for the farm before any was sold off; but reduce it to the ratio of the present size of the farm, say about one third off, and you have a rent of $260, out of which the repairs

were to be paid. Such was the exhausted state of the land, that it scarcely paid six per cent. (after deducting for repairs) on $4,100, the amount of purchase money that I was charged with.

For several years I got but poor returns for my labor, not having the means or energy to improve till 1837. In that year I concluded to run my face, and make an effort towards improvement with lime; and up to 1839, I had put on about 12,000 bushels, at a cost at the kilns of 20 to 22 cents per bushel. By 1840, I had seen and felt the good effects of the lime, and determined to complete the first dressing of all my arable lands, as well as my Cote Brilliant Farm (better known as Gum Bush) of 380 acres, which I had also purchased at a credit for less than $8 per acre, and was situated near by, as Wheatland, my homestead. In that year (1840) I purchased 10,000 bushels of lime, at a cost of 17 cents per bushel delivered at the landing of the canal, distant about four miles from the farms. Here I again had to run my face; but this time I went to the lime burners on Schuylkill, where I would advise all honest Delawarians, that have not limed, to go at once, for to this day honest Delaware faces are in good repute there. They are no repudiators. And while on the subject of lime, I will state that one lime burner, William Mogee, has sold in New-castle county, within the last six months, 145,000 bushels of lime, of which 90,000 bushels have been delivered.

Previous to 1840 I had sown clover and other grass seeds pretty freely—one year as much as 45 bushels; and the same year I purchased 20 tons of plaster. At first I got but poor return even for my lime—I suppose for want of vegetable matter; but when my clover had grown so as to make a swarth or lay for turning under, my crops began to increase even beyond my expectations. The crops for the year 1844, which closed with my late wheat crop, were all got out and sold by the 25th of July, 1845, producing the following results:

Oat crop light—not many sown—crop sold for $209—rental share	$104 50
Corn tillage large—97 acres, including an orchard of 4 acres, not well tilled, produced 3,000 bushels—rental share, 1,500 bushels, at 40 cents - - - - - - -	600 00
The wheat crop amounted to 2,820 bushels, exclusive of brock or rakings—the rental share one half, or say 1,410 bushels, at 90 cents - - - - - - -	1,269 00
	1,973 50
This was grown on two fields, one of which, of 97 acres, a clover ley, well turned under, produced 1,872 bushels, exclusive of brock, which would have made this field amount to over 20 bushels to the acre.	
Add 64 bushels of brock, at 90 cents per bushel - - -	57 60
	$2,031 10

The other field of wheat contained about 60 acres. The product of this field was 948 bushels, exclusive of rakings; or, had they been included, the yield would have exceeded sixteen bushels to the acre. This field had been hard cropped, for the wheat followed corn, which corn had followed wheat stubble of the year previous, without manure or clover. Indeed, this field had produced nine crops in twelve years, with but little

manure at any time, it being farthest from the farm yard; and my plan is never to haul manure to the far side of the farm, whilst I have poor land near by. The principal help this field has had was 40 bushels of lime to the acre, put on in 1838, and two crops of clover turned under; and on a part of the field a crop of oats was turned under that had been injured by the hail storm of 1840.

The rental value of these three crops of oats, corn, and wheat, may then be set down at $2,031 10, the usage of this part of the country being one-half of the grain for rent. In the upper Hundreds, near the manufactories, an additional amount in money would be obtained for the privileges of dairy, poultry, eggs, &c.

The rental value, as above set forth, you will perceive at a glance, now pays an interest of six per cent. on a capital of $33,850. The original cost of the farm, or investment, was, as you will also perceive, $4,100, and that a credit. I will leave you, gentlemen, to calculate the yearly dividends on the investment.

JOHN JONES.

From the Farmers' Monthly Visitor, September 30, 1845.

FRENCH AGRICULTURE.

The *Presse* publishes some extracts from a work presented to the agricultural congress, now sitting at the palace of the Luxembourgh, by the author, M. Catineau Laroche, and entitled *France and England compared with respect to agricultural, manufacturing, and commercial industry, and the consequences to be deduced from this comparison.* It appears from this work that England, in comparison with the extent of its surface, possesses four times more cattle than France. And as it is not possible to pursue a judicious system of agriculture without manure, and as the feeding of cattle is the most productive of supplying manure, it follows that before France can compete with England in agricultural wealth, she must increase her stock of cattle; but in order to do so, she must increase her pasture lands or meadows. "France," says M. Laroche, "possesses but 4,200,000 hectares of natural meadows, or only one-sixteenth of her cultivated soil. From this calculation, it may be easily comprehended how insufficient is her supply of green food, and that it becomes absolutely necessary that she should substitute another to the triennial system at present in use." M. Laroche concludes by stating that, "if the alternate system of cultivation pursued in England was introduced into France, the produce of corn would be doubled within twenty years. Fifty-five years since, the produce of Great Britain was estimated by Arthur Young at three millards. At present it is estimated at five millards seven hundred and twenty-five millions."

[Messrs. Gowen's, Webber's, and Slingerland's statements respecting cultivation, &c., are omitted for want of room.]

APPENDIX No. 30.

ON ARTIFICIAL MANURES.

BY PROFESSOR JUSTUS LIEBIG.

My attention has often been directed to the question whether, acccrding to our experience and the present state of science, a manure might not be composed which could replace the genuine guano in its effects, and whether I could not, by a series of experiments, point out a way of preparing one equal to it in all its chemical and physical properties. You are well aware, sir, that we know with certainty all the elements of the guano, as well as of the urine and solid fæces of men and animals. In like manner, it seems to have verified the opinion which I have laid down in my work on agriculture, that the salts manufactured in the laboratory have the same effect on the growth of the plants, if they are embodied to the fields in the same forms in which the animals furnish them in their excrements. This must be evident to every one who knows that, to produce these compounds in the laboratory, the same agencies and means are made use of which are employed by nature. The fabrication of a manure, equal in its composition and effects to the solid and fluid excrements of animals and men, seems to me one of the most essential demands of our time. * * * The following may be regarded as the essential constituents of a powerful manure, applicable to all sorts of soils:

Earthy phosphates.—The most important of these is *phosphate of lime*, which occurs in nature as a mineral called *apatite*. It is the principal element in the bones, which, it may be observed, have been found most efficacious, if calcined; consequently deprived of their animal matter. The rapidity of the effects of phosphate of lime on the growth of plants depends upon its greater or lesser solubility. Its amount of glue (gelatine) diminishes this solubility, if the soil is rich in vegetable matters, which furnish carbonic acid by their decomposition, and which acid is required for rendering the phosphate of lime soluble in wtaer, and introducing it into the organism of the plants. In the calcined state, the bones act sufficiently quickly; but in those soils in which this cause of solubility is wanting, their action is slower. In my work I have recommended the addition of a certain quantity of sulphuric acid, both in order to render the bones more soluble and to change the neutral phosphate of the bones into gypsum, and into a phosphate which contains more superphosphate of lime. I have been informed that this advice has been most extensively adopted; that the superphosphate of lime has been found to be a most efficacious manure, and that it forms already a most important article of commerce. A second earthy phosphate, not less important, is the *phosphate of magnesia*, which, it is well known, enters, in a still larger proportion than the *phosphate of lime*, into the composition of the grain.

The *alkaline phosphates*, although not originally found in nature, are important elements of the seeds of grain, of peas, beans, &c. A rational farmer must provide them in sufficient quantities to those plants which require them for their development, from knowing human excrements in-

crease the produce in grain in a far greater proportion, because they *contain* alkaline phosphates, than the animal excrements, in which they *do not exist*.

The *alkalies* (potash and soda) must be constituents of every rationally composed manure, because by them the original fertile condition of the fields is preserved. The soil which contains the *alkalies* in too small a quantity is, perhaps, fertile for grain; but it is not necessarily so for turnips or potatoes, which require a great quantity of alkali. By supplying an alkaline manure, fallows for the cultivation of those plants which are grown during the time of fallowing become less necessary.

Sulphate of potash is a constituent of all plants, although in small quantity, as well as *common salt* and *chloride of potassium*, which are found in milk in rather a large proportion. The *salts of lime*, especialy *gypsum*, is an important nourishment for the leguminous plants. Salt is never wanting in all sorts of soils; it is a constituent of all rocks, by the decomposition of which all productive soils are formed, and the cerealia find it every where in sufficient quantity, and in a form capable of being taken up by the plants, *if the alkalies are provided* wherever they are present in too small quantity.

Salts of ammonia.—It can be regarded as certain that the azote of the plants is derived either from the ammonia of the atmosphere, or from the manure which is provided in the shape of animal fluid and solid excrement, and that azotic compounds exercise an effect on the growth of plants only in so far as they give up the azote, in the form of ammonia, during their decomposition and decay. We may, therefore, profitably replace all the azotic substances with compounds of ammonia.

Decaying vegetable matters, which contain carbon, are useful to the fields in so far as they provide a source of carbonic acid; but they are not quite indispensable in manure, if the latter be rationally combined, as the atmospheric air is an inexhaustible source of carbonic acid, from which the plants draw their carbon, if in the manure the mineral substances are provided which are necessary for the assimilation of the carbonic acid. These are the substances which *together* give fertility to the soil; but although each of them may, under certain circumstances, (viz: where the soil is defective in it, or where it is not indifferent to the plant to take up one instead of the other, as, for instance, may be the case with soda instead of potash,) increase the fertility, no *one* of them can be regarded as a manure, according to the common meaning of the word, for the simple reason that only *all of them in certain proportions* will fulfil the purpose for which the common manure is applied. This purpose is the restoration, or an increase of the original fertility, and by manure we must replace all the elements of the plants which have been taken away in harvest, or which are contained in the plants which we are desirous to cultivate.

What, then, are the constituent elements of the soil which we remove by the straw, seeds, tuberculous roots, stalks, &c., of our plants of culture? It is obvious that we must know these first, in order to *restore* them in sufficient quantities. To this we answer by giving the analysis of the ashes of plants and their seeds. Hundred weights of the ashes of the following plants contain—

	Beans,	Straw of Peas,	Potatoes.	Ashes of Clover,	Hay.
Alkaline carbonates - - -	29.38	12.43	4.34	31.63	3.0
Carbonate of lime - - -	39.50	47.81	43.68	41.61	6.9

	Beans,	Straw of Peas,	Potatoes.	Ashes of Clover,	Hay.
Phosphate of lime - - -	6.43	5.15	5.73	11.80	40.8
Phosphate of magnesia - -	6.66	4.37	7.82	0.91	
Sulphate of potash or soda - -	12.40	10.15	–	2.23	8.84
Magnesia - - - - -	–	–	–	–	21.8
Chloride of sodium or potassium -	0.28	4.63	2.8	2.27	3.06
Phosphate of iron, Phosphate of alumina, &c. } -	–	–	–	–	12.7

In these analyses silica has not been taken into account, as it is found in all soils, and need not be supplied. One hundred weight of the ashes of potatoes, and the seeds of the following plants, contains—

	Potatoes.	Wheat.	Beans, (Vicia faba.)
Alkaline phosphates - - -	15.75	52.98	68.59
Phosphate of lime and magnesia -	9.00	38.02	28.46
Phosphate of iron - - -	–	0.67	
Sulphate of potash - - -	15.07	–	1.84
Carbonate of potash and soda - -	51.70		

What is wanting in the 100 of the above analyses is sand, coal, or loss. From these researches, it appears that for stalks and leaves we require other elements than for seeds. The former contain no alkaline phosphates, but they require for their development and growth a rich supply of alkaline carbonates and sulphates. On the other hand, the carbonates are entirely wanting in the seeds, but the latter are very rich in phosphates. It is sufficiently obvious that a rational farmer must supply *both*, as well as all the others. If he supplies only phosphates, and does not restore the alkaline carbonates, his soil will become gradually barren; it will be exhausted in those necessary elements for the development of stalks and seeds, without which no formation of seed can be expected. If he supplies the alkalies, lime, and sulphates alone, in a given time he will get no more grain. All constituent elements of the manure, if they are supplied *alone*, have that great defect—that by them the soil is impoverished in other equally important elements. No *one* of itself can maintain the fertility. Keeping this in view, we may easily judge of the comparative value of artificial and natural manures, and all the various *arcana* which have been praised as *panaceas* for exhausted soils.

It is not less easy to understand why the farmers have such different opinions on the relative value of the constituents of manures; why one whose farm is rich in phosphates produces an uncommon fertility by the application of nitrate of soda, or the supply of alkalies, while another does not see any favorable effect at all; why bones (phosphates of lime) produce in many fields wonders, and are not of the slightest benefit to others, which are deficient in alkalies or alkaline salts. From the composition of animal manures it results, with certainty, that, by applying the latter, (solid and fluid excrements of men and animals,) we supply to the soil, not one, but all the elements which have been taken away in the harvest. Fertility is restored to the field by a corresponding supply of this manure, and it may be increased by it to a certain limit. This will be the more intelligible if we compare the mineral elements of the urine of horses and cattle with the mineral elements of herbs, straw, roots, &c., of our cultivated plants. It will be found that in their quality they are perfectly identical:

66

	Urine of a horse.	Of another.	Of oxen.
Carbonate of lime	12.50	31.00	1.07
Carbonate of magnesia	9.46	13.07	6.93
Carbonate of potash	46.09	40.33	77.28
Carbonate of soda	10.33		
Sulphate of potash	13.04	9.02	13.30
Chloride of sodium	0.55	–	0.30

These salts in the urine of horses amount to nearly 4 per cent., in that of oxen to $2\frac{1}{2}$ per cent., of their weights. If we compare the composition of these different sorts of urine with the composition of the straw of peas, beans, and potatoes, of clover and hay, it will at once be obvious that in stable dung we replace by the urine the alkaline carbonates which we have removed in harvest. What, in this urine, is wanting in phosphates and carbonate of lime and phosphate of magnesia, forms the principal constituent elements of the solid excrements of animals; *both together* (solid excrements and urine) restore the field to its original composition, and thus a new generation of cultivated plants meet with the mineral ingredients necessary for their development. If we further compare the guano and the fæces of men with the composition of the animal urine, the analysis shows (reference, my book on agriculture) that both are entirely defective in *alkaline carbonates*. They contain phosphates and sulphates, as well as chloride of sodium, but no free alkali. They contain phosphate of lime and phosphate of magnesia. In short, their elements are in *quality* identical with the important mineral elements of the seeds of wheat, peas, beans—(reference, the analysis.) The urine of swine is in its composition intermediate between the urine of man and horses.

Analysis of the urine of swine.

Carbonate of potash	12.1	The solid excrements of swine contain principally phosphate of lime.
Phosphate of soda	19.0	
Sulphate of soda	7.0	
Chloride of sodium, Chloride of potassium,	53.1	
Phosphate of lime, Phosphate of magnesia,	8.8	
Traces of iron,		

What the practical results of a knowledge of the composition of these manures are, is clear. If it were possible to provide our fields with the dung of swine in sufficient quantity, we would replace by it, in a soil which contains *silicia* and *lime*, all the remaining elements of the plants. The field might be made fertile for all kinds of plants. We have in it not only alkaline phosphates, the principal elements of the seeds, but also alkaline carbonates, which are required by the leaves, stalks, and roots. This purpose cannot be attained, however, by manuring with guano or human excrements alone, but perfectly so by stable manure, from its containing alkaline carbonates. If I have said that stable manure contains the mineral elements of the nurture of the plants, exactly in a state and condition in which they are furnished by nature—that a field manured by it resembles the primitive state of America and Hungary—this assertion will not be

found exaggerated. It is certain that stable dung contains no alkaline phosphates; but nature does not furnish to the plants these elements even in the most fertile soil, although we find them in large quantity in all the seeds of wild plants. It is obvious, notwithstanding their absence from the soil, that the phosphates are formed in the organism of the plants, and that they originate from the phosphate of lime and magnesia and the supplied alkalies, by an exchange of the elements of both. The alkalies are necessary for forming *alkaline phosphates*, which cannot originate in the phosphate of lime alone. Both together are present in stable dung. In human excrements, and in guano, the alkaline carbonates are entirely wanting. The practice of the farmer, in some places, of supplying to the field not pure guano, but a mixture of it with gypsum, shows clearly that the phosphates of alkaline bases are really formed in the organism of the plants from the phosphate of lime and magnesia, because this mixture (guano and gypsum) contains less phosphate of potash or soda than the guano itself; or, in certain proportions of gypsum, no alkaline phosphates at all, the soluble phosphates in the guano decomposing the gypsum into phosphate of lime and magnesia, and into sulphate of potash. I am far from asserting that we should not provide the fields with alkaline phosphates. The excellent effect of the guano, and of the human excrements, is too well known to question it, and we perceive, from this fact, that plants are in this respect like domestic animals, which, with a normal food, are healthy and strong, but do not fatten. On the contrary, we know that if we prepare the food of these animals artificially, so as to render it more easily digested and assimilated, they are enabled to consume, in a given time, a greater quantity of it, by which all their parts increase in weight. The same happens with plants, if we give them their nourishment in a state most appropriated for assimilation; their capability to attract the other elements from the atmosphere increases, and their development is accelerated. If we recollect that the favorable effect of guano upon our fields depends on its amount of *ammoniacal salts*, of *alkaline phosphates*, and the *other mineral constituents* of the seeds, but that it is defective in *alkalies*, the principal elements of the *herbs*, *straw*, and *roots*, it is easily understood why the opinions of farmers on the value of guano as a manure are so very different. On a soil which is defective in alkalies its effect is small; on a soil rich in them it increases the produce in a remarkable degree; but, as I have already observed, the continued application of guano must gradually diminish the fertility of our fields for a number of plants, because the elements of those organs, of the leaves, stalks, roots, &c., without which the plants cannot be developed and cannot produce seeds, are taken off in the harvest without any restoration of them. I think it, therefore, certain, that the stable dung can replace to a certain degree, but not *vice versa*. A rational agriculturist, in using guano, cannot dispense with stable dung.

In the manufacture of an artificial manure, it must be kept in view that application of stable dung, of human excrements, and of guano, is attended with a great loss, in consequence of the too great solubility of their most efficacious elements; and this must be prevented by artificial means. This is evident, if we remember those countries from which guano is derived. It is known that the collection and preservation of the excrements on the African islands, and the coasts of Peru and Chili, depend upon the scarcity of rain in those countries. The best sorts of guano contain, in fact, more than one-half of their weight of soluble salts, which, if exposed

to the rain, are in exactly the same condition as, under similar conditions, a heap of *salt*. They dissolve in water, and are removed. Some months of rain would deprive those countries of all their riches. The remainder would have lost the greater part of its fertilizing power. Such effects, however, take place upon the guano with which our fields are manured. Only a small portion of its efficacious elements produce the beneficial effect they are capable of doing, the greater part being carried off by the rain. The stable dung is, in this respect, in the same condition as guano. Indeed, its principal elements are already in a dissolved state, and therefore are carried off more easily than those of guano.

A covering for those places in which stable dung is preserved, in order to shelter it from the effects of the rain, has been regarded in Germany as essential for preserving its manuring power. In consequence of the experience that the soluble elements of stable dung are the most efficacious, it has, in some cases, been drawn out with water, and it has been found advantageous to carry *only this fluid* to the fields. I need only refer to the foregoing analyses of the urine of animals in order to see upon *which elements* of it this effect depends.

The reason why, in certain years, the influence of the best and most plentiful manuring is scarcely perceptible, is, that during the moist and rainy springs and summers the *phosphates* and *other salts with alkaline bases*, as also the *soluble ammoniacal salts*, are entirely or partly removed. Art must find out the means of reducing the solubility of the manuring substances to a certain limit; in a word, of bringing them into the same state in which they exist in a most fertile, virgin soil, and in which they can be best assimilated by the plants.

I am occupied with a series of experiments, which lead me to hope that that this problem can and will be solved. If it succeed, as I have no doubt it will, in combining the efficacious elements of manure in such a way as that they will not be washed away, their efficacy will be doubled. If in this manner the injurious consequences of the present system of draining be removed, agriculture will be based upon as certain principles as well arranged manufactories. Manufactories of manure will be established, in which the farmer can obtain the most efficacious manure for all varieties of soils and plants. *Then*, no artificial manure will be sold whose exact amount of efficacious elements is not known; and this amount will be the scale for determining its value. Instead of the uncertainty of mere empiricism, all the operations of agriculture will be carried on with certainty; and instead of waiting the results of our labors with anxiety and doubt, our minds will be filled with patience and confidence.

I am, sir, your obedient servant,

DR. JUSTUS LIEBIG.

GIESSEN, 1845.

In Muspratt's English Patent for Improvements in the Manufacture of Manure, communicated by Dr. Liebig, of Giessen, Germany, the method proposed is thus described:

"In making manure according to the invention, I cause carbonate of soda or of potash, or both, to be fused in a reverberatory furnace, such as is used in the manufacture of soda-ash, with carbonate or phosphate of lime,

(and with such fused compounds I mix other ingredients, as hereafter mentioned,) so as to produce manures; and such composition, when cold, being ground into powder by edge stones or other convenient machinery, the same is to be applied to land as manure. And in order to apply such manure with precision, the analysis and weight of the previous crop ought to be known with exactness, so as to return the land the mineral elements in the weight and proportion in which they have been removed by the crop.

"Two compounds are first prepared, one or other of which is the basis of all manures, which I shall describe as the first and second preparations.

"The first preparation is formed by fusing together two or two and a half parts of carbonate of lime with one part of potash of commerce, (containing, on an average, sixty carbonate of potash, ten sulphate of potash, and ten chloride of potassium or common salt, in the hundred parts,) or with one part of carbonate of soda and potash, mixed in equal parts.

"The second preparation is formed by fusing together one part of phosphate of lime, one part potash of commerce, and one part of soda ash.

"Both preparations are ground to powder; other salts or ingredients, in the state of powder, are added to these preparations and mixed together, or those not of a volatile consistency may be added when the preparations are in a state of fusion, so that the manure may represent, as nearly as possible, the composition of the ashes of the preceding crop. This is assuming that the land is in a high state of cultivation; but if it be desired to grow a particular crop on land not in a high state of cultivation, then the manure would be applied in the first instance suitable for the coming crop, and then, in subsequent cases, the manure prepared according to the invention would, as herein described, be applied to restore to the land what has been taken therefrom by the preceding crop.

"*Preparation of manure for land which has had a wheat crop grown on and removed therefrom.*—Take of the first preparation six parts by weight, and of the second preparation one part, and mix with them two parts of gypsum, one part of calcined bones, silicate of potash, (containing six parts of silica,) and one part of phosphate of magnesia and ammonia.

"And such manure is also applicable to be used after growing barley, oats, and plants of a similar character.

"*Preparation of manure for land which has had a crop of beans grown thereon and removed therefrom.*—Take fourteen parts, by weight, of the first preparation, two parts of the second preparation, and mix them with one part of common salt, (chloride of sodium,) a quantity of silicate of potash, (containing two parts of silica,) two parts of gypsum, and one part of phosphate of magnesia and ammonia.

"And such manure is also applicable for land on which peas or other plants of a similar character have been grown and removed.

"*Preparation of manure for land on which turnips have been grown and removed therefrom.*—Take twelve parts, by weight, of the first preparation, one part of the second preparation, one part of gypsum, and one part of phosphate of magnesia and ammonia.

"And such manure is also applicable for land where potatoes or similar plants have been grown and removed."

He remarks that other manures may be prepared for plants, "if the matters of which the plants are composed, and the quantities, are first ascertained, by burning the plants and analyzing the ashes, and then combining

the manure according to the analysis. The manure so made is to be applied to the land in quantities as great or greater than the quantities of the elements which have been removed by the previous crop. It should be stated, that where the straw of wheat and other similar plants which require much silicate of potash is returned to the land as manure, that is considered to be the best means of restoring the requisite silicate of potash to the land; in which case the silicate of potash would be omitted."

Communicated for the New York Farmer and Mechanic, for publication.

AMERICAN INSTITUTE—FARMERS' CLUB.

Source of carbon and nitrogen in plants, as derived from the soil: by Fromborg, of the Agricultural Chemistry Association of Scotland.

The opinions of Mulder, of Utrecht, founded on great chemical investigation, are, that the organic constituents of soil—namely, the humic, ulmic, geic, crenic, and apocrenic acids—after being combined with ammonia, are taken up and assimilated by plants, being all of them very soluble in water, and possessing polybasic properties, by which they are enabled to form combinations with potash or soda, ammonia, lime, magnesia, and oxide of iron, in which several of those bases are present at the same time;

That ammonia is formed in the soil by the combination of the nitrogen of the air with hydrogen in its nascent state, as liberated during the decay of vegetable and animal substances in the soil.

From careful experiments, Mulder establishes the following facts:

1. Rain-water and air are insufficient to suport the life of plants.
2. Rain-water, wood-ashes, and air, are equally so.
3. That the aqueous extract of humus contains too small a portion of matter to afford plants all they require.
4. That ulmic acid from sugar is advantageous to their growth.
5. That humic acid from garden mould is very useful in vegetation.
6. That humate of ammonia from peat is advantageous to the growth of plants.
7. That charcoal and ashes are inferior to arable soil, or to the substances mentioned in Nos. 5 and 6.

Fromborg says the well known fertilizing action of charcoal requires, indeed, no other explanation than its characteristic property of condensing gases.

Mulder observes that a number of little plants were produced in solutions of potato starch, acetate of potash, nitrate of ditto, binoxolate of ditto, and even in chloride of calcium, sulphate of soda, and common alum. I have seen them in solutions of neutral tartrate of potash and of sulphate of alumina.

Miguel, of Rotterdam, the skilful botanist, examined these plants and recognised them as being of the genus cryptococeous, ulvina, hydrococis, sirocrocis, and Septomitus.

Professor Liebig says that traces of ammonia can hardly be detected in large quantities of rain-water; and although he assumes that a pound of rain-water contains one-fourth of a grain of ammonia, yet it is obvious that, in a continuous rain, only that part which falls first contains that

quantity! What falls subsequently would soon be without ammonia at all. The minute quantity contained in the air, above a field, is far from being a sufficient source for all the nitrogen contained in the plants growing upon it.

Professor Johnston says: The ammonia produced in the air from decomposed vegetables and animals can but imperfectly be restored to the soil. The greater part is washed down by rains into the sea, and is lost to the soil. What remains in the air will undergo a continual decomposition by electricity and by thunder storms.

Mulder's theory is, that the ammonia in the soil serves as a medium to transfer the oxygen of the air to putrefying substances.

Many think that the doctrine of aerial nutrition of plants is right, because it exhibits a degree of simplicity and beauty consonant with the other works. [Read by H. Meigs.]

The result of a trial of various manures, reported in the Royal Agricultural Society's Journal, led to the following conclusions:

1. Nitrate of soda, nitrate of potash and soot, have a tendency to increase the produce of wheat, both straw and grain.

2. That common salt has a slight tendency to increase the produce of grain, and to decrease the weight of straw—(mark the *weight* of straw, that it does not diminish the bulk;) and that common salt increases the weight per bushel of the grain. Thence it may, from these properties, be advantageously used as an auxiliary to the other manures.

3. That sulphate of soda has no visible effects upon the wheat crop. The slight variation in yield of straw may be fairly attributed to accidental circumstances, such as variation of soil, &c., as no two patches can be *perfectly* equal in every respect.

[At a meeting of the American Agricultural Association.]

PREPARED MANURES, AND THEIR EFFECT UPON CROPS.

BY MR. PELL.

* * * * * * * * * *

I apply straw to the cattle-yard; it absorbs the liquid excrement, and rots. What is long or partly unrotted I apply to hoed crops; what is fine I mix with the eleven requisites, and apply as a top-dressing. It may be advisable to apply the straw to the ground, and plough it when unrotted. To grow grains, give the soil straw of its kind; for potatoes, their vines; grapes, their vines; to apples, their branches; and so of all. The droppings of cattle are the best material to grow grasses, as they feed on grass; those of horses fed on grain, for the growth of cereals. Onions are grown year after year by only returning the tops to the ground. In Virginia, had the refuse of the tobacco plant been returned to the soil, she would not now be barren. The bad farmer is injured by the vicinity of well manured land, as manure has an affinity for oxygen, hydrogen, ammonia, &c., floating in the air, and attracts them to the provident farmer's land.

Formerly, I applied composts of various things, and had wonderful results; I dared not omit any one, as I knew not which had produced the

result. Now, science, by analysis, shows what is necessary. By these composts, I grew a squash to weigh 201 pounds, the heaviest on record; and a cabbage to weigh 44 pounds. By it I grew wheat to weigh 64 pounds, rye 60 pounds, oats 44½ pounds. When Sprengle made known his analysis, showing that eleven substances are necessary to all good soils, I found that my compost, by chance, had them all, and twenty other enriching ingredients.

Previous to 1840, my orchards bore only every other year. Since then, I make them bear every year; and this year, a bad one for fruit, found my manured trees full, and those not manured barren. The drought of this year was fatal to fruit; yet my manured trees had abundant moisture, and were fruitful. I prefer the manure of decayed vegetable matter to the excrement of cattle, as the material that makes and supports the animal has been extracted, and the excrement is not so rich on that account. If the vegetable matter be rotted and its ammonia fixed by charcoal dust, all the chemical substances are present. Thus, rotted vegetable matter is more beneficial than the dung of cattle, quantity and quantity alike.

A most valuable manure is the liquid remaining after the boiling of bones. It is very offensive unless disinfected. When hot it is not offensive, but becomes so when cold. It is a jelly when cold. By the application of charcoal dust to the hot liquid, the jelly, when cold, is not offensive. In this state it may be made into compost with other substances. In that condition it is a most valuable manure. At present large amounts of the liquid are thrown into the rivers. I prevailed upon a grinder of bones to save his liquid by charcoal, and he now sells what formerly he hired carried away. I have used it with great advantage, both on arable and meadow land.

Charcoal is one of the most valuable manures. It is the most powerful absorbent known. It takes from the atmosphere oxygen, hydrogen, nitrogen, ammonia, &c., and holds them while the weather is dry. During rain it absorbs eighty per cent. of water, and releases the gases to descend to the earth to fertilize it. When the weather becomes dry it parts with the water, and absorbs from the air the gases again. This it continues almost perpetually, as it is nearly indestructible. When applied to the earth, the trees, plants, and grasses are found to have it adhering to their roots, ready to impart gases and moisture as wanted. Trees packed in it have remained green for eighty days, while others, without it, have died in like circumstances. Hams and salt meats are preserved perfectly when packed in it. I preserved apples in perfect condition for one year in it. If spread over compost heaps, barn yards, stable-floors, in privies, it absorbs the ammonia, prevents offensive smells, fixes the volatile gases, and thus makes a valuable compost.

Ashes applied to sandy soils are valuable; and, on some soils, leeched are as good as unleached. I have known land, too poor to grow eight bushels of corn, made to produce forty-five bushels by ashes alone; and they are more valuable on a sandy soil than any other, except marly clay. They enable the sandy soil to retain its moisture—a great point. They are used to great advantage on Long Island and in New Jersey. They stimulate growth, as does plaster. Sown broadcast on grass, the effect is perceptible at a great distance. The yield the first year, on sandy soils in grass, will pay the expense of applying forty bushels to the acre. They give to the soil silicate of potash, which is needed to form stems.

Ashes have two actions on soils, viz: Chemically, by alkali they neutralize acids; and mechanically, by rendering sandy soils more tenacious. Muck is made valuable by them, when mixed in compost; the acid of the muck is destroyed by the alkali, and fermentation follows.

Lime has been used by me to great advantage. I prefer oyster shell lime, as it contains no magnesia, which most stone-lime does. I think oyster-shell lime has a tendency to lessen in growth the stem and leaves, and increase the fruit and seeds. I put on barren or worn-out land 300 bushels of oyster-shell lime, and it grew wheat to a weight of 64 pounds per bushel: with the wheat I sowed one bushel of clover seed and half a bushel of timothy seed per acre, and the next year cut 2½ tons, and the second year 3 tons of hay per acre. I have found it of great advantage in potato culture; the potatoes do not rot in the ground, while neighboring unlimed ones *all* do. They are mealy and fine, and do not rot after gathering, and have been free of rot in dry, wet, and average seasons. I think it destroys the fungus or insect, if either be the cause of rot.

Bone dust I have used, and find it most valuable, and advise its use, especially on soils long cultivated, destitute of phosphate of lime. It is the most efficacious manure that can be used on an exhausted soil, but will do better on dry calcareous soil than on such as contain alumina. It should be mixed with earth to ferment before spreading. There should be used from twelve to twenty bushels to the acre. It seems best on turnips In compost it is valuable, as it yields phosphates largely. It is said that in England, where, on lands, it had been applied twenty years before, its effect could be seen to a yard I trust the exportation of bones from our country will soon cease.

I have used guano successfully and unsuccessfully. Mixed with earth, and applied to plants in close contact, it was injurious; applied in weak solution to grass land and green-house plants, its effect was wonderful. My experience shows that *its method* of use will determine *its value*. In composts I have found it very effective.

Night soil is one of the most valuable manures. In this country, as well as in England, great prejudice prevails against its use in agriculture or gardening. For ages it has been used in Asia, and particularly in China. In France, in Belgium, Bohemia, Saxony, all the German confederacy, and Sweden, its destruction or waste is prohibited by law. In England and America it is thrown into the rivers, to befoul them, and the fish which devour it are eaten instead of vegetables grown by it. As manure, six loads of it have been found to produce 650 bushels per acre of potatoes, while, on the same ground, one hundred and twenty loads of horse manure yielded only 480 bushels.

In conclusion, I have to remark that the main stay of the farmer is his barn-yard manure. Yet this varies in quality, according to the material of which it is made, and the manner of making. Thus the droppings of cattle fed on straw and turnips are far less valuable than those of cattle fed on hay and oil-cake; and it is economy to feed hay and oil-cake rather than straw and turnips. So in manuring: that which is leached by rains and volatilized by the sun is less valuable than the unleached and unsunned.

PREPARATION OF MANURE

In the review of a work of Mr. Bernay's, chemist, on the subject of manures, &c., the Mark Lane Express quotes the following method of preparing the farm-yard heap:

"The importance and advantages of the arrangement and compilation of the manure heap are too well known to require any observation from us; but we cannot lay by this practical work without giving the author's directions for preparing the farm-yard heap.

"'It should be a rule to heap it on as small a space and as compact as possible. The ground on which it is placed should consist of a stiff clay, or be bricked over. It should commence about half a foot below the surrounding ground, and be situated so as to cause all the water from the manure to run into the tank. The conduit leading to the latter should be well covered in, so as not to allow spring-water or rain-water to collect in it. A layer of gypsum is now to be spread on the flooring, and the heap is to be commenced by covering the whole bottom, with the exception of about half a foot on each side. On every foot height of manure a layer of gypsum is to be spread, sufficiently thick to appear white. When the heap is completed, or before, the contents of the tanks are to be poured on by degrees, in quantity sufficient to moisten the head well, but so that little will run back into the tanks. By these means the following advantages will be obtained: Firstly, the cartage of the urine will be rendered unnecessary, and some labor and expense saved; secondly, the gypsum of the farm-yard heap will be dissolved; and, thirdly, by the addition and evaporation of the water of the urine, the decay of the manure will be hastened. If the method recommended of strewing the stable floorings with gypsum be followed out, of course but a small quantity of it will be necessary. A thin layer may then be strewn on every two feet high of the heap; and when completed, the top and sides should be sprinkled with it. The heap itself should not be higher than six feet, for many reasons.'"

From the New England Farmer.

DISSOLVING BONES IN SULPHURIC ACID.

At a special meeting of the Royal Agricultural Society of England, Mr. Pusey, having adverted to the great discovery of the economical and efficient employment of bones as manure, when dissolved by maceration in sulphuric acid, proceeded to read extracts from Mr. Hannam's prize essay on the subject, of which the following is a condensed statement:

In an experiment on turnips, the crop from dissolved bones was not only more abundant, but less attacked by insects than that dressed with undissolved bones, and the plants far more rapid in their growth the first month, and a gain of a month in the end. The results of several experiments by Mr. Hannam were then stated, from which it appeared that 2 bushels of dissolved bones produced as good results as 16 bushels of undissolved; that 8 bushels dissolved would greatly surpass 16 bushels not dissolved; and that 4 bushels in a state of solution would be a proper quantity per acre, producing crops greatly superior to 16 bushels of undissolved crushed bones, and the cost less in proportion to the effect produced. [We suspect the effect on the *first* crop only is here referred to.]

The proportions used had generally been, of acid one-half the weight of the bones, but one-third or even one-fourth of the bones might be employed: the proportion of water had generally been 100 times the weight of the acid, but 50 or 25 times would serve the purpose efficiently. It must be understood that the more finely pulverized the bones are before mixing, the better.

Mr. Thompson stated that he had last year found 4 bushels of dissolved bones, applied in the form of compost, fully equal to 20 loads of farm-yard manure, there being no perceptible difference in the crop throughout the field. Mr. T. suggested, that as it was often difficult for a small farmer to find a vessel of sufficient capacity to contain the mixture, it might be found a simple substitute to form a sort of pond, puddled with clay, in which the mixture could be made. When the solution was complete, the clay might be mixed with the compost.

A letter from Mr. Spooner, of Southampton, was read, in which he stated that he had last year used bones and sulphuric acid in compost, for turnips. He had prepared it by placing 1¾ bushel of finely ground bones in a tub, with half their weight of acid, diluted with four times the quantity of cold water. After some hours, a few bushels of fine mould and some coal ashes were added, so as to make the whole amount to 15 bushels of compost. The mixture was applied in the drills at the rate of little more than 2 bushels per acre, and, as Mr. Spooner states, successfully rivalled 16 bushels of bones applied to an acre of superior quality.

There seems to be some difference of opinion as to what constitutes the fertilizing principle of bones. Professor Liebig, in the third edition of his Agricultural Chemistry, says: "The efficiency of bones as a manure does not depend upon the nitrogenized (organic) matter, as has been generally but erroneously supposed, but upon their phosphate of lime." Professor Johnston, and many others, attach much to the gelatine, which slowly decomposes and affords to plants nitrogen. The gelatine or organic part of bones is, chemically, like horn, hair, wool, and skin; and as these substances are all known to be good manures, the gelatine of bones must operate in the same way.

The oil or fat in fresh bones, if applied to the soil without any preparation, I think cannot be of much use, as it consists entirely of carbon, and the elements of water—oxygen and hydrogen. When buried in the soil, it is almost as indestructible as charcoal. If muscle, lean meat, and animal fat, are mixed in a heap, and exposed to the action of the weather, even in the hottest part of summer, the muscle (lean meat) is soon decomposed, but the fat will run together and be converted into a substance resembling old cheese or spermaceti: the fat in bones will probably do the same.

There are several ways in which a farmer may make use of bones for manure, in the country, where there are no mills to grind them. He can break them up, and apply them to the soil in the broken state; they will in that way gradually give out nitrogen and phosphate of lime for at least "three lives."

They can be burnt, and then they are easily broken up, and can be dissolved in sulphuric acid; the fire, however, drives off all the animal matter. Or they can be boiled in strong lye, and in a few hours they become disintegrated, and as fine as meal. By this process the nitrogenized part, the gelatine, is mostly driven off, and the air of a room in which they are boiling smells as strong of ammonia as the hold of a guano ship; but the

oil and fat are converted into a kind of soap. The whole can be mixed with muck or soil, and will make a first-rate manure for the turnip crop.

I have boiled some bushels of horn-piths into a pulp, in three hours; the harder bones require some longer time. Without doubt, if there was a portion of sulphuric acid mixed with the lye, the bones would come to pieces much sooner, and the ammonia would probably be fixed by the acid, and formed into sulphate of ammonia; unless it should combine with the potash of the lye, or the lime of the bone, as it has a stronger affinity for these.

As stated near the commencement of this, rather more than one-half of dry bone is phosphate of lime—in the proportion of 51½ per cent. of lime, and 48½ of phosphoric acid. By mixing about one-half the weight of sulphuric acid diluted with water, double decomposition ensues—one-half the lime of the bone combines with the sulphuric acid, and forms gypsum. The other part of the lime combines with a double equivalent of phosphoric acid, and super or biphosphate of lime is the result. Phosphate of lime is very insoluble; biphosphate is much more soluble, and is readily taken up by the rootlets of plants, especially by the wheat crop. About one half the ashes of the grain of wheat is phosphate of lime. Phosphate of lime and potash are found in the ashes of all our forest trees, but it is so very insoluble that it is not extracted in the process of leaching for soap making; and, unquestionably, much of the value of spent ashes depends upon the phosphates they contain.

L. B.

[Messrs. Stabler's, Hallowell's, and Norton's experiments, &c., on manures, Mr. Pickett's account of guano, and the description of its poisonous effects, are omitted for want of room.]

APPENDIX No. 31.

CANADA TARIFF.—CANADIAN CUSTOMS.

These duties are to be counted as sterling money, and to take effect on the 6th day of April next. (1845.) These duties are *in addition* to the duties imposed on the same goods by the British Parliament. This act repeals all former duties except that on wheat.

Animals, viz: Cows and heifers, each £1; calves, each 5*s.;* goats, each 2*s.* 6*d.;* horses, mares, geldings, colts, fillies, foals, each 10*s.;* kids, each 2*s.* 6*d.;* lambs, each 1*s.;* oxen and bulls, and steers, each £1 10*s.;* pigs, (sucking) each 6*d;* swine and hogs, each 5*s.;* sheep, each 2*s.*

Grain, viz: Barley, the quarter, 3*s.;* buckwheat, bear, bigg, the quarter, 3*s.;* oats, the quarter, 2*s.;* maize or Indian corn, (the quarter to be 480 lbs.) the quarter, 3*s.;* rye, beans, peas, the quarter, 3*s.;* meal of all the above grains, and of wheat not bolted, the 196 lbs., 2*s.;* wheat flour, per bbl. of 196 lbs., 6*d.;* bran or shorts, the cwt., 3*d.*

Hay, the ton, 6*s.*

Straw, the ton, 3*s.*

Provisions, viz: Butter, the cwt., 2*s.;* bacon, the cwt., 5*s.;* cheese, the cwt., 2*s.* 6*d.;* hams, the cwt., 5*s;* meats, salted or cured, the cwt., 2*s.;* meats, fresh, of all kinds, the cwt., 4*s.*

Candles: Sperm or wax, the lb., 2*d.;* all other kinds, when imported otherwise than by sea, the lb., 1*d.*, and if imported by sea, five per centum ad valorem.

Potatoes, the bushel, 3*d.*

Salt: Imported otherwise than by sea, the barrel, weighing net 280 lbs., 2*s.* 6*d.;* imported by sea, the ton, 1*s.*

Tobacco: Unmanufactured, the lb., 1*d.;* manufactured, the lb., 1*d.;* cigars, the lb., 2*s.;* snuff, the lb., 4*d.*

Wood, viz: Pine, *white*, and in proportion for any smaller quantity thereof, per 1000 cubic feet, £1 5*s.; red*, per 1000 cubic feet, £1 15*s.;* oak, per 1000 cubic feet, £2 15*s.;* birch, per 1000 cubic feet, £2 10*s.;* ash, elm, tamarac or hacmatac, and other woods not herein charged with duty, per 1000 cubic feet, £1 5*s.;* staves, standard or measurement, per standard mille, £1 5*s.;* puncheon, or West India, white oak, per standard mille, 10*s.;* ditto red oak, per standard mille, 7*s.* 6*d.;* do. ash, per standard mille, 4*s.;* do. barrel, per standard mille, 4*s.;* deals, pine, per Quebec standard hundred, 15*s.;* do. spruce, per do., 7*s.* 6*d.;* plank, boards, and all kinds of sawed lumber not herein charged with duty, per 1000 superficial feet, inch thick, 7*s.* 6*d.;* and so in proportion for any greater thickness.

Ashes of all kinds, bark, burr stones unwrought, berries, nuts and vegetables used principally in dyeing, cotton-wool, coals, fur skins or peltries, undressed or unmanufactured, hemp, flax and tow, hides, (raw,) pig iron, saw logs, soda ash, tallow, lard, fish-oil, fish, salted or cured, oysters, lobsters, and turtles, for every £100 of the value, £1.

A table of imperial duties on imports into Canada; compiled conformably with the revenue laws now in force.

Beef, fresh, free.
Beef, salted, 3*s.* per cwt.

Bacon 3*s*. per cwt.
Bran or shorts, free.
Butter, 8*s*. per cwt.
Candles, spermaceti, 15 per cent.
  Do. all others, 7 per cent.
Cheese, 5*s*. per cwt.
Eggs, 4 per cent.
Fins and skins of sea animals, 15 per cent.
Fish, fresh, free.
Fish, dried or salted, 2*s*. per cwt.
Fish, pickled, 4*s*. per barrel.
Flax, free.
Flour of wheat, 2*s*. per barrel.
Flour and meal, other, free.
Fruits, fresh, free.
Hams, cured, 3*s*. per cwt.
  Do. fresh, free.
Hay, free.
Hemp, free.
Hides, raw, free.
Hops, 4 per cent.
Live stock, asses and mules, free.
Bulls, free.
Calves, under 1 year, free.
Cows, and all cattle under 4 years, free.
Goats, free.
Hogs, free.
Horses, free.
Colts, under two years old, free.
Lambs, free.
Cows and oxen, four years old and upwards, free.
Sheep, free.
Lumber, free.
Manures, of all kinds, free.
Meal, free.
Meat, fresh, free.
  Do. salted, 3*s*. per cwt.
Pork, fresh, free.
  Do. salted, 3*s*. per cwt.
Potatoes, free.
Poultry and game, 4 per cent.
Oats, free.
Seeds, 4 per cent.
Seeds, garden, free.
Straw, free.
Soap, 7 per cent.
Tallow, free.
Tobacco, manufactured, 7 per cent.
  Do. unmanufactured, 4 per cent.
Vegetables, fresh, free.
Wood and lumber, free.

APPENDIX No. 32.

TRADE, ETC.

From the Mark Lane Express.

THE CORN CROPS OF EUROPE.

We extract from the *Gazette d'Augsburg* the following article on the crops of 1845 in Europe :

" According to the custom we have adopted, we shall divide our account of the results of the last crop into two parts—one referring to the east, and the other to the west of Europe. For several years past the east threatened us with sterility. It first of all began in Russia, spread over Poland and Prussia, and appeared even this year likely to diffuse itself in the east of Germany. Experience has generally proved that in the boreal latitude the rainy years are more sterile than the dry ones. This fact has again been confirmed during the last years. It was humidity that diminished the crops a few years ago in Russia, and which produced the like effect in Poland, Galicia, and Upper Silesia, in the course of last year. In Germany the humidity has not produced any unfavorable consequences, but in certain countries. There are others, on the contrary, which have suffered from want of rain. The results of the crops are, in the mean time, far from being satisfactory, and, from the calculations which have been made, will not suffice the public consumption.

" It is far from our intention to represent the situation of things in more dreary colors than belong to it ; but we do not wish, and we ought not, to exaggerate the advantages of it, desirous as we are of attaining our present object, which is to furnish an exact appreciation of actual circumstances. We shall separately name the different countries, and indicate the supplies they stand in need or can dispose of.

" Russia will have sufficient corn for the whole empire, without purchasing any foreign corn. Its governments are in a position to assist mutually each other, but it is very doubtful whether they can send much corn abroad.

" The crops of Poland are not sufficient for its general consumption ; and, unless it has been previously supplied, will suffer from a scarcity, or be obliged to receive corn from abroad. But whom can one have recourse to when one's neighbors have only had themselves but middling crops, and have not wherewith to supply the deficiency ? Money also is scarce in Poland, and important sums cannot be sent abroad to purchase corn.

" The kingdom of Prussia has greatly suffered last year and this from inundations, which have ravaged precisely its most fertile countries ; and want, which is generally felt there, is on the point of transforming itself into actual famine.

" The news from Pomerania agrees in stating that the results of the last crops are very mediocre.

" In the Grand Dutchy of Posen only a middling crop has been obtained, and anterior provisions can alone prevent a scarcity. The author does not remember having heard such numerous and general complaints, unless it be in the years 1804 and 1817. God grant that the unfortunate events of

that epoch be not again reproduced! There are in this province whole countries where the usual corn sellers will be obliged themselves to make purchases the next spring. The situation of Galicia is still worse. The price of rye rose 60 per cent. immediately after the crops. It is still on the rise.

"In Hungary, which is usually so productive, the government has been obliged to lay in large stores of corn to prevent a famine. The hope entertained of having good crops has been still more cruelly disappointed than in Silesia.

"In Austria, Moravia, and Bohemia, the results of this year's crop are below those of the average ones, and must scarcely suffice for the general consumption.

"If we consider the west of Germany, we find, first of all, that the crops in Saxony have not precisely failed, although they are very far from being abundant. The same may be said of the provinces of Brandenburg and of Magdeburg.

"Bavaria, like other countries, has suffered greatly this year from hail-storms and water-spouts. The results of the crops have, in consequence, been diminished, as likewise by the state of the atmosphere, which has shown itself but little favorable to the cultivation of corn.

"Wurtemburg, the country of Baden, Westphalia, and the Rhenish provinces, have been better treated; but the disease which has ravaged the potato crop will be severely felt. Nevertheless, the potato crop has been generally good throughout western Germany. It will supply many deficiencies in the crops of other places, although they are not so much grown as in other parts of Germany.

"Belgium and Holland have had but bad crops; and the news from France sufficiently proves that this year has not been a productive one.

"Spain occupies but an inferior rank among corn-growing countries; still, reports from this country do not mention that the crops have been deficient.

"England, where the States of the European continent generally find a market for their surplus corn, appears to-day to be reassured on the wants of its internal consumption, or at least the alarming news which arrived from that country has been succeeded by much more favorable intelligence. Those who count upon corn supplies from the Baltic and provinces of the North Sea will be greatly deceived. The prices of these productions will first of all be very high; and, in the second place, the quantities that can be supplied, very small. A great quantity of wheat has this year been struck by blight; and this disease, which has spread throughout Germany, Poland, and Hungary, has deteriorated the quality of the corn, as well as diminished the quantity. Further, it cannot now be accurately known whether at a later period England will not be reduced to supply itself from abroad, for it is well known that it is only in case of an abundant crop that enough corn can be grown for the country. In the contrary case, she will look to supplies from America, or from the countries bordering on the Black Sea.

"In Scandinavia, that is to say, Denmark, Norway, and Sweden, the crops have not been satisfactory. In a few words, then, it may be said that for many years past there has not been so unfavorable a year as the present one; and if it be added that last year only furnished but indifferent crops in comparison with the preceding ones, this circumstance ought to give rise to measures being taken to prevent the danger which threatens us."

CURED PROVISIONS, AND CATTLE.

A return of cured provisions imported in the half-year, to the 5th of July, 1845, and of live cattle imported in the last three years, has been printed by order of the House of Commons, on the motion of Mr. Grogan, M. P. for Dublin city. It hence appears that the total quantity of cured provisions imported into the United Kingdom in the period above mentioned, was: Of salted beef, 46,347 cwt.; of salted pork, 23,860 cwt.; of hams of all kinds, 2,423 cwt.; and of bacon, 16 cwt. only. A very insignificant portion of these cured provisions was retained for home consumption, namely: 2,363 cwt. of beef, realizing a revenue (in the shape of duty) amounting to 401*l.*; 1,191 cwt. of salt pork, producing a revenue of 459*l.*; 1,349 cwt. of ham, producing a duty of 992*l.*; and 13 cwt. of bacon, yielding an amount of duty of 20*l.* The total quantities re-exported as merchandise was: Of beef, 4,304 cwt.; of pork, 6,341 cwt.; and of ham, 470 cwt. The rest was taken for ships' stores, including 44,672 cwt. of salt beef, (junk,) 12,563 cwt. of salt pork, and 525 cwt. of ham. The greater portion of the salted beef was imported from the Cape of Good Hope, and the Hanseatic towns figure for 2,650 cwt. The larger portion of the salted pork came from the Cape of Good Hope, the Hanse Towns, and Prussia, and half of the ham from the Hanseatic towns, the rest being distributed for the most part between Hanover, Oldenburgh, Holland, and the Peninsula, (including both Portugal and Spain.) Of live cattle and other animals there were imported into the United Kingdom in the year ended July 5, 1845, 6,466 oxen and bulls, 2,503 cows, 118 calves, 3,969 sheep, 42 lambs, and 411 swine and hogs. In 1843–'44 there were imported 1,294 oxen and bulls, 531 cows, 60 calves, 220 sheep, 12 lambs, and 322 swine and hogs. In 1842–'43 there were imported 3,578 oxen and bulls, 1,193 cows, 86 calves, 727 sheep, 12 lambs, and 563 swine and hogs. From which figures it results that the importation of oxen and bulls has nearly doubled since the year 1842–'43, that the import of cows has more than doubled itself during the same period, that sheep have increased from 729 to 3,969, that calves have remained steady, and that, lastly, swine and hogs have fallen off. Such are the effects of the new tariff, as illustrated by the return before us.

From the American Agriculturist.

STAVES.

Since the late reduction of duty in Great Britain on staves from the United States to 28*s*. per 50 cubic feet, they will become an article of considerable export. It is important, therefore, that they should be properly prepared for the English market. For the benefit of those farmers engaged in the stave business, we subjoin, from a circular recently received here, the principal directions to fit them for the British market.

Size.—The standard to which staves are now limited is 72 inches long, 7 inches broad, and 3 inches thick, and it is always very desirable to get the staves of this full length and breadth, length especially. By making them 72 inches long, they suit at once for the sides and ends of all puncheons for the West India trade, and also for the sides of sugar hogsheads. For brewers' casks, both for the home and export trade, there is a large de-

mand for white-oak staves, 30, 37, and 47 inches long, 7 inches broad, and $1\frac{1}{4}$, $2\frac{1}{4}$, and 3 inches thick. The present standard thickness of Canada pipe staves, viz: $1\frac{1}{2}$ inch, is very suitable for coopers in general; but 1 inch, 2 inches, $2\frac{1}{2}$ inches, and 3 inches, are all used, although the thick sizes are considered less valuable, and scantlings with large proportions of those in them do not take the market so well. Besides the full length of 72 inches, the only other sizes at which staves should be cut are 42 inches and 33 inches. These lengths would answer the home cooper trade generally, and suit exactly for West India casks, &c. The lengths of 30 inches to 33 inches are also the sizes required for beef tierces; and if split at the proper thickness of an inch, or rather less, or if they were of such thickness as would split into an inch, large quantities of them might be disposed of. These are what have hitherto been called pipe staves. As regards small staves, the only length it would be worth sending is that of 42 inches. Of these there are three kinds which require to be specified: 1st, rum puncheon; 2d, molasses puncheon; 3d, sugar hogshead. Rum puncheon and molasses puncheon staves are cut 42 inches long, and should stand at least 1 inch thick in the rough state. A similar stave, for spirit casks, &c., 45 inches long, and $1\frac{1}{4}$ thick, would generally find a ready sale. Some hogshead staves are 42 inches in length and three-quarters of an inch thick. Particular attention should be paid to make them stand about an inch more than the lengths stated, to allow for working them to the net size.

From the Southwestern Farmer.

TRADE IN CORN-MEAL.

We see no reason why corn-meal should not be a great article of export from this region of the Union to the West Indies, South America, and even England, (or, rather, we should say *especially* to England,) for in that country corn cannot be raised. There are establishments in some parts of the country for preparing it by kiln drying, in such a way that it can be kept sweet in tropical climates for many months. In Mississippi we have now corn in silk, (May 15th,) at a date when those who export to the West Indies have not planted theirs. If, then, we had the same enterprise among our people that our brother farmers have in Illinois, Indiana, &c., we might have our mills, coopering shops, and packing-machines, as well as the corn-grower, all busily employed furnishing the foreign market with "*fresh corn-meal*" before the Illinois corn is in tassel.

In connexion with this subject, we call attention to the following communication, copied from the New Orleans Bulletin. It is from the pen of a Norseman. N.

CONSUMPTION OF CORN-MEAL IN THE WEST INDIA ISLANDS.

The consumption of corn-meal and other American produce throughout the British West India islands, since the emancipation of their slaves, has considerably increased. The negro, formerly limited by law to a certain quality and quantity of food, has now his choice of both, as far as his means,

obtained by labor, will admit; hence the consumption of pork, beef, butter, lard, cheese, flour, bread, etc., etc., formerly luxuries, are now in general use, and increasing to an immense extent, while the consumption of corn-meal, the only food during slavery, is again reviving, and its use on the increase, from the following causes.

In the Antilles, Jamaica, Barbadoes, and Trinidad excepted, the lands are too valuable, "under a protective system, and at the low price of life's necessities in the United States," to produce corn, yams, casadas, or other substitutes for bread; besides which, the operations of growing and manufacturing sugar cannot be accomplished without combined labor; hence the laborer, allured by the magic of money, which he can readily obtain for his labor, neglects even the small patch of ground on which, as a bondsman, he was entirely dependant for a few pennies to purchase a bit of pork or white bread—"then luxuries."

Barbadoes consumes now from 20,000 to 25,000 barrels of corn-meal annually; whereas, previous to the emancipation, not a barrel was imported. In this fact may be found the basis for my previous argument. Anterior to the emancipation of slavery, a great many small farmers, called ten-acre holders, existed by raising corn and ground provisions for the use of the planter to feed the slaves; so abundant at times were their crops, that I have known corn to be shipped from Barbadoes to St. Thomas. The natural decrease in labor, since the emancipation, by the same number of hands, has, in order at all to approximate former crops, caused an increased demand for laborers, which has drawn this class of agriculturists from their former occupations, finding it more to their advantage to render services for ready money, supplying their wants in market. I do not for a moment pretend to say that Barbadoes is altogether dependant on foreign imports of corn-meal: 25,000 barrels per annum are but a small portion of sustenance for a laboring population numbering at present 85,000 souls; but I feel fully assured the same causes which have created the present demand are on the increase. Trinidad has increased her population much since the emancipation of slavery. It has, however, as yet, for its extent of country and fertility of soil, a small population, raising within themselves a good deal of corn, and receiving some supplies from South America. The consumption can at present only be computed at 10,000 barrels, while that of Demarara is about 15,000.

Jamaica, with a laboring population of about 325,000 souls, consumes comparatively less than the former-mentioned islands: 30,000 barrels may at present be considered the extent. Large tracts of lands have, since the emancipation, become divided among the laboring classes, producing large quantities of substitutes for cheap breadstuffs. This circumstance, combined with the almost spontaneous growth of fruit and vegetables, makes the laboring classes at certain seasons less dependant on foreign supplies; but as the population is and must continue on the increase, so follows an increase of wants. St. Croix, St. Thomas, and St. John's are permanent, being fixed by law to seven quarters of meal for each laborer; which amounts, at St. Croix, according to a statement furnished me by the Royal Danish Chamber of Commerce at Copenhagen, to 9,500 puncheons, or equal to 38,000 barrels. St. Thomas and St. John's consume about 6,000 barrels. St. Croix consumes but few other American provisions except flour, of which about 4,000 barrels of American; the balance of her consumption, about 3,000 barrels of flour, large quantities of beef, pork, etc., are supplied

by the mother country—Denmark. Yet that island, only 100 square miles, with a population of 34,000, employs yearly about 10,170 tons American shipping. For the general trade of the West Indies, meal in barrels is found most saleable. St. Croix and Porto Rico, however, require their supplies in puncheons, of 800 lbs. net, (such as shipped from Brandywine mills,) both on account of its better keeping, and use for the puncheons for rum and molasses.

From the foregoing illustrations, I will now venture upon a general computation of the consumption of corn-meal throughout the West Indies. Antigua, Dominica, Granada, Montserrat, Nevis, St. Kitts, St. Lucy, St. Vincent, Tobago, Guadaloupe, Martinique, the Virgins, and Bahamas, with a population of 184,000 souls, must, in common calculation, consume

Annually about 200,000 barrels, say - - -	200,000 bbls.
Barbadoes, 25,000; Trinidad, 10,000 - - -	35,000 "
Demarara - - - - - - -	15,000 "
St. Thomas, St. Croix, and St. John's - - -	44,000 "
Porto Rico, 40,000; Jamaica, 30,000 - - -	70,000 "

making 364,000 bbls. corn-meal annually. A branch of trade so easily at our command has hitherto been neglected, or but partially and imperfectly commenced; whereas, with this article, the supplying of every other article of provisions from our port would follow. That such a trade is important to New Orleans, I will illustrate by a statement of the imports into Kingston, Jamaica, for three years, up to the 19th of this month, the day I left Kingston:

	1843.	1844.	April 19, '45.
Flour, bbls. - - - -	65,464	98,900	25,700
Flour, half bbls. - - -	1,735		
Corn-meal, bbls. - - -	38,346	22,039	20,096
Bread, bbls. - - - -	25,975	26,000	2,543
Pork, bbls. - - - -	13,292	25,640	1,197
Corn, bbls. - - - -	24,478	47,360	16,500
Tobacco, hhds. - - - -	91	105	41
Beef, bbls. - - - -	1,800	1,900	315
Tongues, half bbls. - - -	1,500	1,100	315
Butter, firkins - - - -	15,365	16,100	1,500
White-oak staves - - -	353,265	64,200	21,000
Wood hoops - - - -	320,110	218,970	11,390
Lard, kegs - - - -	11,500	9,000	2,231

These are independent of imports to the outports, such as Falmouth, Montego Bay, &c.

The average net price of corn-meal for twenty years throughout the West Indies may be computed at $12 per puncheon, or $2 50 per bbl.—a price sufficient to recompense its manufacture.

During my late visit to Jamaica, I had the mortification to be told of and see corn-meal received from New Orleans unfit for that or any West India market; the shippers having acted in their own wisdom, cannot, by their losses, judge of the market. But to avoid similar occurrences, I will again repeat that the meal must be equal to the best Philadelphia kiln dried, made from the best yellow corn, packed in barrels of 196 lbs. net; and so packed,

that, on opening the barrel, it is perfectly full. The barrels should be clean when shipped, have a plug for convenience of sampling, well lined, and riveted. These regularities, so simple in their nature, properly attended to, place us at once in full and fair competition abroad; whereas, otherwise, we will linger for years laboring under prejudices against this article, when received from New Orleans, as was formerly the case with our flour in the West India markets, (and is yet in the Rio market,) without any known cause but want of attention in its manufacture at the beginning.

DANE.

NEW ORLEANS, *April* 29, 1845.

Liverpool prices current of American produce, made up from actual transactions, to January 4, 1846.

Five per cent. additional is charged on duties stated, except on sugar and breadstuffs. Provisions *for export or ship stores* pay no duty. Hams and bacon in pickle pay pork duty.

REVIEW OF THE MARKET.

LIVERPOOL, *January* 3, 1846.

DEAR SIR: The commencement of another year, the fourth since the opening of the trade, finds the American provision business established on a firm basis. Prejudice has almost entirely disappeared; and most of the articles in the preceding prices current are judged only by their real merits comparatively with previous customary supplies. In curing, cutting, and packing, there is still something to learn. Neatness, cleanliness, and sightliness are continually requisite, as well as an adaptation as closely as possible to the uses and customs of our markets.

Prices have been favorable to imports during most part of the year, and throughout have been safe for extensive operations until *now*, for it is feared much of the shipments on the way will result disastrously. The reports as to prospects of a supply of food in this country were and are certainly gloomy enough, but the unreasonable prices demanded, and, in too many instances, paid in the United States, cannot have much effect in brightening them, as the enhanced value puts them quite out of the reach of the laboring classes, which natural result appears be be overlooked by shippers.

Beef.—The imports of beef have reached a safe maximum, being about equal to a reasonable demand. Prices have opened high, and would easily retain present value were packers more careful to retain the reputation of their brands; but, out of the numerous parcels already received, only *one* has opened equal in style to previous shipments. The great error has been in curing with dirty pickle, insufficient in quality and strength; but some have so far forgotten their own interests as to place the coarsest and roughest parts of their cattle in tierces marked "prime mess." The unprofitable results of such shipments will, perhaps, prevent a repetition of such management.

Pork.—There has not been a satisfactory business in pork. The imports have been to usual extent, of which more than one half are still in stock. The first arrivals of last season were entirely satisfactory, but the after imports were more carelessly handled, and could not compete with Irish or Hamburg. Some very superior has lately arrived, and held at a price beyond the best Irish. It would be well if this superiority could always be maintained, although, unless prices give way in the United States, a profitable business cannot be done at present, prices here showing a tendency to give way rather than advance.

Ashes.—The trade in pot and pearl ashes does not increase. The imports have been 1,921 barrels of the former, and 827 of the latter, which have nearly all gone into consumption, at about present quotations. The irregularity of quality prevents an increased business.

Butter.—The great scarcity of grease-butter caused prices to advance to 50*s.* during the season, and there was none left over. The make and import of butter have been so much increased this season that we cannot look for such high rates to rule the coming year, although the quantity wanted will be very large. Butter for eating has not yet become an article of profitable import, nor will it until the duties are reduced. There are some small parcels here, and on the way, for which 60*s.*, in bond, must be considered an extreme quotation.

Cheese.—There has been a pleasant trade in cheese throughout the year. Prices in New York have got above our level at present, and put a stop to extensive business, but this is believed to be only temporary. At or under present prices, the consumption of England has capabilities for even yet greatly increasing imports. The quality is generally unexceptionable.

Seeds.—The business in seeds has been profitable during the past season when shipped with proper judgment. The imports of flaxseed this year have been unusually early, and it is hoped will not continue to be so extensive the balance of the season. With a fair supply, the market promises well, but at prices reduced from the last season. Fine cloverseed is expected to bring long prices, as the crops are short, and quality inferior throughout.

Hemp.—The unequal and inferior quality of hemp has been frequently noticed. Until packers give this subject necessary attention, little good can be done in this market; but were once a character established, an immense consumption would be had in England, as in strength and length of fibre American hemp is unequalled.

Wool.—The same fault, though in a less degree, of irregularity in packing, has been found with American wool, which is rapidly assuming much importance in this country. An extensive wool-broker in London, in writing to another part of the world, on this subject, uses language so well suited for the United States that I do not hesitate quoting it:

"The remedy appears to us, on this side of the water, so easy, that we feel astonished at the growers being so blind to their own interests.

"The men who shear the sheep can be told to cast aside any black or gray sheep's coats, and pack them separately;

"And the wool from sheep shorn in the grease can surely be kept apart, and packed separately;

"And the very coarse, half-bred, and low, kempy, native fleeces, can surely be packed separately;

"And the white, good, fine, and clean fleeces can be packed by themselves.

"If the care which we have been advocating were taken with your wools, the grower or dealer would, in making out his invoice, classify his produce as follows:

"A	1 to 10,	10 bales,		all fine clean fleeces, ewes, &c.
"B	11 to 12,	2	"	clean lambs'.
"C	13 to 15,	3	"	native fleeces.
"B	16 to 17,	1	"	greasy ewe fleeces.
"E	17,	1	"	greasy lambs' fleeces.
"F	19,	1	"	black and gray, lambs' and fleece.
"G	20,	1	"	locks and pieces picked up and shaken from the straw after shearing.

"We have no hesitation in saying, that, if the farmers can be induced to operate upon these remarks, and sort their wool properly, giving a faithful representation of the contents of the several packages, as above, their wool will acquire that popularity in the market to which their improved growth already entitles them; and, in short, their full value will be secured."

The imports of wool have been over 3,500 bags, but only a small portion has found buyers, the bulk of the arrivals having come in during December, when there was a total disinclination for business among all classes, and it is too early in the year to note any increased demand.

Hides.—During the first six months of the year the market was generally heavy, and prices declined fully $\frac{1}{2}d.$ per pound, but they have since experienced some slight improvement in value, although the demand is far from brisk, and the sales of last month do not exceed 800 hides, at $3\frac{1}{8}d.$ for New York, and $3\frac{1}{4}d.$ to $3\frac{3}{8}d.$ per pound for Philadelphia; leaving the present stock 7,300 hides, against 1,900 at this period last year. Import 36,970, against 31,500 in 1844, and 17,300 in 1843.

Sole leather.—Since the abolition of the customs' duties on leather, there have been some considerable imports from the United States, (estimated at about 25,000 sides,) the greater part of which, being tanned with hemlock bark, was exceedingly difficult of sale, although offered at very low rates: that portion tanned with oak bark found buyers; but the prices obtained were generally unremunerating to the shippers.

Lard.—Within the last week we have had large arrivals of lard from New Orleans, previous to which we had had heavy receipts from Philadelphia and New York. The price is, therefore, down at least 5*s.* below highest value of the season. The demand for culinary purposes is still limited, but is enough, unless further arrivals interfere, to clear off present stock without much further reduction. Many packages injure the lard so as to unfit it for eating purposes, by being charred inside when seasoning. The lard, consequently, is smutted.

Tallow.—The imports continue to increase, and the quality of many brands is now standard. At a price equal to Russian, any quantity can be placed; but this will not afford a profit at prices now ruling in America. There is a poor prospect of any advance. Only one third of the consumption of tallow in Great Britain is imported in the average of years, so that any increase of the home supply, and with the present consumption of meat in England it must be materially added to now, has a serious effect on prices of foreign.

Staves.—The importations of the year are equal to 516 M., chiefly of

W. O. puncheon. The sales during the month are limited, and stock is accumulating. Good W. O. pine have been sold at £14 15*s.* to £15 per M. The best demand is found for those suitable for cleaving into sugar hogshead staves of red or white oak. If an article for that purpose could be introduced, so that the staves would cost £7 10*s.* to £8 per M., this market would take off a large quantity.

Flour and breadstuffs.—In all business matters the last few weeks have been anxious and perilous. The resignation of Sir Robert Peel, the advent of Lord John Russell, and the recall of Sir Robert Peel, following in such sudden succession, are so full of meaning, that trade (suffering at same time by the panic in the money market) has been paralyzed; and, until the opening of Parliament shall have put us in possession of the real intentions of government, we cannot look for a prosperous revival. That an important change is about being made in our corn and provision laws all parties are agreed, and that the change will be a final settlement of this long vexed question is also fully believed; but its extent and conditions no man out of the government can tell, and speculation is various and useless. The guess which will be found nearest the truth, perhaps, is one which says a fixed duty on wheat, commencing at 12*s.*, and falling yearly to a minimum, will be proposed, accompanied with the compensation to landholders of taking from land one of its peculiar burdens, the poor-rates, and making them payable out of the general taxation of the country.

Whichever way this great question is settled, so it be settled, the United States will reap immense benefits. Another month will give us full particulars.

So small a portion of the railway schemes have reached maturity, that all fear for their effect on the money market has disappeared, and discounts have become comparatively easy.

Flour has been sold to a considerable extent, at 28*s.* to 29*s.*, in bond, which is 4*s.* to 5*s.* under highest price a few weeks since. The duty has advanced a step. Indian corn is not easy to sell at 34*s.*, in bond, although it is generally believed it will be admitted free of duty. Black-eyed peas are known here as kidney beans, and are free of duty since 1st of June, 1845.

With compliments of the season, I am, respectfully,

JAMES M'HENRY.

LIVERPOOL, *January* 1, 1846.

The commencement of the past year was ushered in by the prospects of the greatest commercial prosperity, and the realization of those continued steady with us for eight months, when the first rumors of a bad harvest came on us in such a form as not to be mistaken or trifled with; and with the past experience of the evil working of our corn laws, prudent men, foreseeing the certain result of an export of bullion to pay for foreign corn, immediately decided on contracting their engagements, and preparing for that tightness in the money market which was sure to follow. This, joined to the immense amount of capital invested or promised for all kinds of railway stock, produced a panic which has now continued for three months; and though it certainly has caused much individual suffering, still the general tone of commercial matters is healthy, and trade, though in some measure paralyzed for a time, is not seriously injured, as may be evidenced by the fact that money is becoming more easy, discounts lower, manufacturers in full employ, the working classes in the receipt of large wages, and the consumption of all produce unusually great; along with this, the agricultural population, as a whole, are in a more prosperous state, the shipping interest remunerating the owners, and the formation of railways over the three kingdoms giving ample occupation to every one disposed to be employed. If our recent political changes were once arranged, the corn laws fixed on a permanent and just basis, and the general policy of our government known, commercial confidence would be at once restored; and enjoying, as we do, peace with all the world, we have reason to look forward with good hopes for the year on which we have entered.

As to our trade with the United States, we have not much general news to communicate since our last. The usual dulness which generally prevails at this season of the year, with the rumors, in every case greatly exaggerated, of the almost certainty of a collision between the governments

of Great Britain and the United States on the Oregon question, all tended to keep us in a state of disquietude, and to limit operations. We are glad, however, on the receipt of the President's message, to see that, though in some points rather warlike, still it showed some disposition for an amicable settlement; and while with one hand the President displays no disinclination for war, he as evidently with the other offers the branch of peace in the form of a decided modification of the tariff; thus following in *our* rapidly extending sound principles of free trade, the light of which appears to be gradually spreading over the most *antiquated* nations of Europe.

Cotton has experienced some variation in prices during the month, owing solely to the impression that difficulties might arise with the United States; but there is so much good feeling for peace and conciliation rising up among the intelligent commercial community of both countries, that this impression cannot be used to force up prices, and sales have gone on at a full average to meet the current demand of the manufacturers, without a variation of more than one-fourth pence per pound.

Wool.—We continue to receive small shipments of wool, which is and will continue to come more into favor. The quality of the staple of some considerable portion is very good; but the Americans, so far, do not sort it properly, but mix all qualities together without due care, thus injuring the general character of the whole shipment. The sales made in last month have been very trifling, at rates under our December quotations.

Beef.—In this article we must do the curers the justice to say that they have all but monopolised our market for the supply of our commercial navy. It is true that some curers have, partly from inattention and partly from design, no doubt been induced to pay less attention to cut, cure, and regularity of packing; they must, however, be told that this is bad policy for their own interests. The expenses on good and bad are equal, and inferior brands will be always looked on with suspicion, and realize lower prices, perhaps, than their actual value—quality with us, in every case of food, being the first object. The sales of the month past have been very trifling, at our prices noted above; but in this article, as in all others, we expect a decided improvement.

Pork does not improve. We find a growing dislike for this article; though offered fully 12 per cent. below Irish, yet it does not sell. This is owing to the soft nature of the pork itself, and partly to the want of that neatness and care which characterise the Irish brands of this article. There have also been a number of true complaints that it does not do for long voyages, and that the extra waste is more than equivalent to the difference between it and Irish.

Cheese.—The arrivals of cheese have not been large, and yet, strange to say, fully equal to the demand. We can account for this most satisfactorily from two causes. The first is, that we have a very heavy make of English, which has been pressed freely on the market; and, secondly, the price of American has so advanced as not only to equal, but in reality to be higher than our own make; and though the quality has no doubt much improved, and is good, yet the large mass of the consumers naturally prefer home make when to be bought at as low or lower rates. We must reduce our quotations 1*s.* *a* 2*s.* per cwt.; but it would require a further fall of 4*s.* *a* 5*s.* before quantity could be sent into consumption equal to last year.

Lard.—At last we have an ample supply of this article, as importers and holders will find, to their cost, before they clear off their present stocks.

The sale has been very limited indeed, and prices must be quoted fully 2*s.* lower, with a downward tendency; and, from present prospects, we shall go down still further before sales to extent can be made.

Tallow continues rather dull. The heavy supplies, at the commencement of last month, operated as a check on free buying; still, holders are very firm, and will not give way 3*d.* to effect sales, under the impression that this dulness is but temporary.

Hides have not altered in value. The amount of sales has been rather limited; but prices have been firmly supported, and in this month we expect to clear off most of our stock at our quotations.

Hemp has improved decidedly during the month, owing to an advance in Russia of 30*s.* per ton, and very small arrivals from the States. We have been able to realize an advance of 20*s.* to some extent, which is likely to be maintained.

Ashes.—We have no change for the better. This market for the season has not shown a limit for a margin for shipments, but we think we have now passed the lowest point.

Cloverseed remains steady at our quotations. Very trifling arrivals of new, but our recent advices from the States quote prices which would leave a serious loss to the shipper in this market, unless we advance still further.

Flaxseed.—The demand has not yet commenced; the arrivals so far are equal to former years, but the quality of the seed inferior to last season. The character of American seed has also suffered with us from the fact that the hogsheads do not contain the proper quantity, many of them proving one half bushel short—sufficient to destroy that confidence which exists towards Dutch seed in this market.

Lead in limited supply, and wanted. The recent arrivals have been taken off freely at our quotations.

Oils remain unaltered in value. The recent arrivals from the States have not given satisfaction, from the fact that most parcels were more or less adulterated.

Tobacco remains firm. The stock on hand is about equal to last year. The demand is steady from the manufacturers, who, in general, are bare of stock.

Oil-cake.—We have received very little so far this season, though several heavy shipments have arrived in London. The quality of what we have is very good, and the condition, from its being all in casks, very superior, selling freely from £9 15*s.* *a* £11 per ton.

Corn.—The recent extraordinary political changes have caused great excitement in this article, as it is well known that the contemplation of a proposed change in our sliding-scale of duties was one (and that not the least) reason of the late apparent disunion in our cabinet. Rumor now says, and we think with truth, that our present government has decided on finally placing this question at rest, either by a total repeal of the duty altogether, relieving the landed interest from some taxes which they deem peculiar to themselves, or else by affixing a low standard—say 4*s.* *a* 6*s.* per quarter as a permanent duty, which, with the cost of transport, they may consider as an ample protection for the agricultural interests. We merely state these as rumors, as nothing certain is known, nor likely will be until after the 22d of January next, when Parliament is to assemble. In the mean time, large quantities of all kinds of breadstuffs have been daily arriving from almost every port in the United States, proving the immense resources of

that country, if the policy of our respective governments was conducted on the broad principles of doing the greatest possible benefit to the greatest number. Our arrivals have been all bonded of course, the importers acting on the belief that a change must be made, which certainly would benefit bonded produce, and would depress free. Our quotations show the present current value at which a fair amount of business is doing, and, from the reasons already stated in this circular, we look forward that any change in the value of United States breadstuffs must be for the better.

With our best wishes for a year of prosperous trade to our friends, we are, respectfully,

J. & C. KIRKPATRICK.

From Willmer & Smith's European Times of January 4, 1846.

I.—IMPORTS INTO THE UNITED KINGDOM.

An account of the imports of the principal articles of foreign and colonial merchandise, in the ten months ended 5th of November, 1845, compared with the imports of the corresponding ten months of the years 1843 and 1844.

Articles.		Quantities imported. Ten months ended 5th November, 1843.	1844.	1845.
Animals, living, viz.—

We have selected the foregoing statistical tables from an English publication called "Burn's Glance." It is issued twice a year, and forms a most valuable sheet of reference to the merchant, manufacturer, importer, or exporter of goods, in proof of which we give the following:

WHITEHALL, *July* 27, 1843.

SIR: I am directed by Mr. W. E. Gladstone to return you his best thanks for the copy you have been so good as to send him of your very useful publication, which is now regularly taken in for the use of the Board of Trade.

I am, sir, your obedient servant,

STAFFORD H. NORTHCOTE.

It may be obtained of Messrs. Willmer & Rogers, European Times office, New York.

COTTON IN GERMANY.

"Our cotton business has again increased materially this year, and sales were—

In 1845	22,940 bales	All United States and Texas cotton.
1844	20,961 "	
1843	14,192 "	
1842	11,779 "	
1841	8,565 "	

"The imports into Hamburg were—

	Bales.	From U. States.	From West Indies and Brazil.	Indirect, East Indies and England.
In 1845	67,306	30,318	8,745	28,243
1844	64,997	19,179	7,306	38,512
1843	75,434	26,240	8,681	40,513
1842	60,895	12,705	10,746	37,444
1841	62,118	24,123	14,738	23,257

"An immense number of emigrants have left our place to seek your hospitable shores, and we expect to find the grand total about 32,000. They were embarked under the following colors: about 140 Bremen vessels, 50 American, and 12 other vessels; and, as far as known, have all safely reached their destination.

"We hope these remarks will prove of some interest to you; and in closing them, we beg to be allowed to sign as

"Your friend and servant."

VESSELS EMPLOYED IN THE FOREIGN TRADE OF THE UNITED KINGDOM.

An account of the number and tonnage of vessels, distinguishing the countries to which they belonged, which entered inwards and cleared outwards in the ten months ended 5th November, 1845, *compared with the entries and clearances of the corresponding ten months in the years* 1843 *and* 1844, *stated exclusively of vessels in ballast, and of those employed in the coasting trade between Great Britain and Ireland.*

From Willmer and Smith's European Times of February 4.

PROPOSED REDUCTION IN THE BRITISH TARIFF.

The following tables show the changes which the British ministers intend to propose in the British tariff:

DUTY FREE.

Resolved, That the duties of customs chargeable upon the goods, wares, and merchandise hereafter mentioned, imported into the United Kingdom, shall cease and determine, viz:

Animals, living, viz: asses, goats, kids, oxen, bulls, cows and calves, horses, mares, geldings, colts, foals, mules, sheep, lambs, swine and hogs, pigs, sucking; bacon; beef, fresh or slightly salted; beef, salted, not being corned beef; bottles of earth and stone, empty; casts of busts, statues, or figures; caviare; cranberries; cotton manufactures, not being articles wholly or in part made up, and not otherwise charged with duty; enamel; gelatine; glue; hay; hides, or pieces thereof, tawed, curried, or in any way dressed, not otherwise enumerated; ink for printers; inkle, wrought; lamp-black; linen, manufactures of linen, or of linen mixed with cotton or with wool, not particularly enumerated or otherwise charged with duty, not being articles wholly or in part made up; magna græcia ware; manuscripts; maps and charts, or parts thereof, plain or colored; mattresses; meat, salted or fresh, not otherwise described; medals, of any sort; palmetto; thatch manufactures; parchment; pens; plantains; potatoes; pork, fresh; pork, salted, not hams; silk, thrown, dyed, viz: silk singles or tram, organzine, or crape silk; telescopes; thread, not otherwise enumerated or described; woolens, viz: manufactures of wool, not being goats' wool, or of wool mixed with cotton, not particularly enumerated or described, not otherwise charged with duty, not being articles wholly or in part made up; vegetables, all not otherwise enumerated or described; vellum.

CORN.

Resolved, That in lieu of the duties now payable on the importation of corn, grain, meal, or flour, there shall be paid, until the 1st day of February, 1849, the following duties, viz:

If imported from any foreign country:

Wheat.—Whenever the average price of wheat, made up and published in the manner required by law, shall be, for every quarter,

	s.	d.
Under 48*s*., the duty shall be for every quarter	10	0
48*s*. and under 49*s*.	9	0
49*s*. and under 50*s*.	8	0
50*s*. and under 51*s*.	7	0
51*s*. and under 52*s*.	6	0
52*s*. and under 53*s*.	5	0
53*s*. and upwards	4	0

Barley, beer, or bigg.—Whenever the average price of barley, made up and published in the manner required by law, shall be, for every quarter,

	s.	d.
Under 26*s*., the duty shall be, for every quarter	5	0
26*s*. and under 27*s*.	4	6

	s. d.
27*s*. and under 28*s*.	4 0
28*s*. and under 29*s*.	3 6
29*s*. and under 30*s*.	3 0
30*s*. and under 31*s*.	2 6
31*s*. and upwards	2 0

Oats.—Whenever the average price of oats, made up and published in the manner required by law, shall be, for every quarter,

Under 18*s*., the duty shall be, for every quarter	4 0
18*s*. and under 19*s*.	3 6
19*s*. and under 20*s*.	3 0
20*s*. and under 21*s*.	2 6
21*s*. and under 22*s*.	2 0
22*s*. and upwards	1 6

Rye, peas, and beans.—For every quarter, a duty equal in amount to the duty payable on a quarter of barley.

Wheat, meal, and flour.—For every barrel, being one hundred and ninety-six pounds, a duty equal in amount to the duty payable on thirty-eight gallons and a half of wheat.

Barley meal.—For every quantity of —— pounds, a duty equal in amount to the duty payable on a quarter of barley.

Oatmeal.—For every quantity of one hundred and eighty-one pounds and a half, a duty equal in amount to the duty payable on a quarter of oats.

Rye meal.—For every quantity of —— pounds, a duty equal in amount to the duty payable on a quarter of rye.

Pea meal and bean meal.—For every quantity of —— pounds, a duty equal in amount to the duty payable on a quarter of peas or beans.

And that from and after the said 1st day of February, 1849, there shall be paid the following duties, viz:

	s. d.
Wheat, barley, beer or bigg, oats, rye, peas, and beans, for every quarter	1 0
Wheat meal, barley meal, oatmeal, rye meal, pea meal, and bean meal, for every hundred weight	0 4½
If the produce of and imported from any British possession out of Europe:	
Wheat, barley, beer or bigg, oats, rye, peas, and beans, the duty shall be for every quarter	1 0
Wheat meal, barley meal, oatmeal, rye meal, pea meal, and bean meal, the duty shall be for every hundred weight	0 4½

‖ Including tallow candles.

APPENDIX No. 33.

JAMES BOGARDUS'S PATENT ECCENTRIC UNIVERSAL MILL.

A patent was granted fourteen years ago to James Bogardus, of the city of New York, for a mill called the "Eccentric Universal Mill," which, on account of its importance, has been extended for fourteen years more, by special act of Congress. From the great importance of this invention to every branch of industry, it is deemed advisable to notice it in this report; for, although patented fourteen years since, the entire change which it introduces in the operation of grinding has delayed its successful introduction, and many parts of the country are not yet acquainted with its advantages.

The discovery of this simple principle has opened a new field to scientific inquiry. Mr. Bogardus has freely communicated its advantages to other arts—for instance, the polishing of dies, and the planishing of stone, glass, or metallic plates. Nothing is ventured in the prediction that the time is not far distant (when its practical application is better understood) when the specula of telescopes will, by its means, be constructed with as little expense as ordinary mirrors.

But, however difficult its scientific investigation, the practical working of these mills has already resulted in the following facts and advantages:

1. In other mills, power has to be applied not only to grind, but also to throw out, by centrifugal force, the substance ground. In this mill the peculiar motion of the plates will of itself discharge the ground substance; thus saving all the ordinary waste of power.

2. From the relative motion of the two plates, there is much less friction between them, and consequently much less direct power is required to turn the mill.

"This mill of Mr. Bogardus is of that class of invention of which but few are made in centuries. Mills are nearly the oldest machinery on record, and yet all others, however various their form, have been constructed on one uniform principle, namely, one stone or plate being stationary, and the other revolving, which, by its rapid revolution, communicates a centrifugal force to the substance introduced between the plates, and thus subjects it to their grinding action; whereas, in Mr. Bogardus's mill, the principle is entirely new, and unquestionably his original invention.

"In this mill, both plates revolve in the same direction, (with nearly equal speed,) on centres, which are apart from each other one inch, more or less—the centre of the one, or axis thereto affixed, resting on and revolving upon a stationary point; whilst the prime mover, by means of a belt or gearing, communicates motion to the other plate. The circles which are cut in the plates act like revolving shears, cutting every way, which, when in operation, causes a peculiar cutting, wrenching, or twisting and sliding motion, admirably adapted for every species of grinding. From the position of the two centres, it is named the *Eccentric Mill.* The beautiful and singular motion of these mills, which originated with himself, he has now brought to perfection, after years of study and experiment; and if the statements of those by whom these mills have been already

used are to be regarded, they must eventually supersede all other mills for all purposes of *hulling*, *cutting*, and *grinding*.

" The following are some of the advantages of mills worked on this principle :

" 1. The peculiar motion of the plates will, of itself, discharge the ground substance, so that many substances can be ground thereby which would altogether choke other mills.

" 2. In other mills a given point in one of the plates continually describes the same circle on the other ; but in this mill it traverses on the other plate, at an infinite variety of angles, every point within two concentric circles apart from each other, twice the distance of the centres of the plates, thereby rendering the wear and tear of the plates uniform, and preserving the grinding action of every point.

" 3. In other mills, the grinding power of each point increases with its distance from the centre ; but in this mill, every point from the centre to the circumference has the same grinding power. A considerably smaller mill will, therefore, effect a given purpose, and the Eccentric Mill is therefore more portable than other mills.

" 4. The ever changing action of the mill, and the quick discharge of the substance ground, prevent it from becoming heated, so that the Eccentric Mill may be profitably employed in grinding substances which, in other mills, would be either spoiled or deteriorated in quality—or, by their melting, be impossible to be ground. If other mills were driven with that speed which can be safely applied to the Eccentric Mill, they would be made red-hot in a few minutes.

" These mills have been successfully introduced for the following purposes :

" Hulling rice, coffee, and olives;

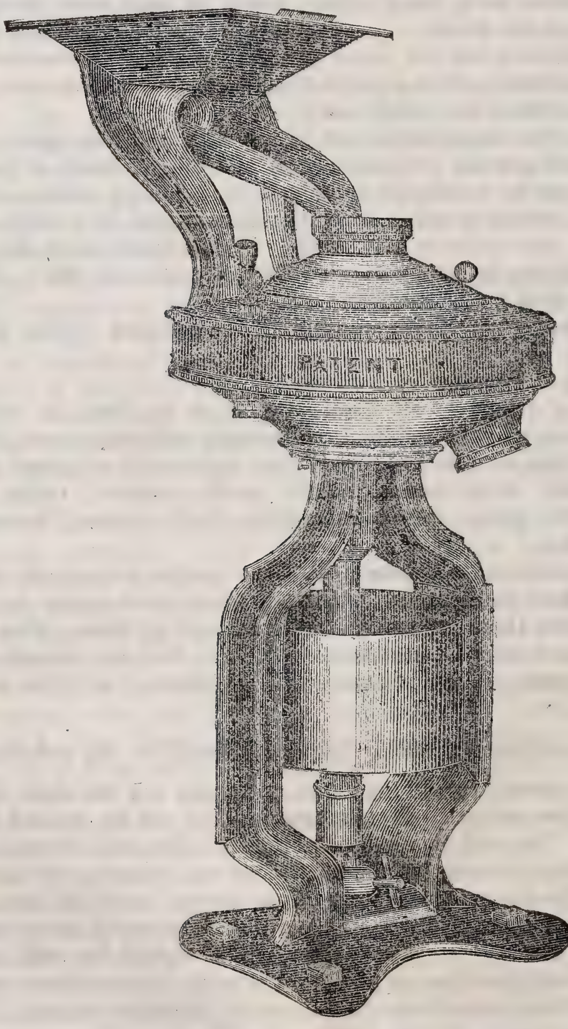
" Grinding grains of all kinds ; paints of all kinds, in water or in oil ; iron, zinc, copper, and gold oars, plumbago and manganese, bones for manure and bones for refining sugar, flint and quartz, charcoal, plaster, putty, printers' inks, drugs and dyestuffs, snuffs, mustard, coffee, spices, loaf sugar, starch, gums, resins, asphaltum, India rubber, flaxseed, and oil-cake, &c., &c.

" Of the substances enumerated, some cannot be ground at all by other mills. In short, the Eccentric Mills are more economical in the power required to drive them, and in the labor of tending them ; they are less costly for the work they do, and more portable ; they are capable of being applied to purposes for which other mills are useless ; and the wear and tear is trifling."

Directions for using Bogardus's mill for dry substances.

The mill should run to the right, and make not less than three hundred revolutions per minute. Nearly any quantity can be ground by increasing the speed. The mill is regulated to grind fine and coarse, by the under-screw, on which the end of the shaft revolves ; turning the screw to the left will bring the plates together and cause the mill to grind finer. The regulating screw is held firmly in any position, by a small screw placed against its side. There are three reservoirs, which should be well supplied with oil. The *first* is on the top of the upper plate : two or three table-spoonfuls of oil should be poured into this reservoir, through a small hole made in the top of the mill for that purpose. The second reservoir is the box,

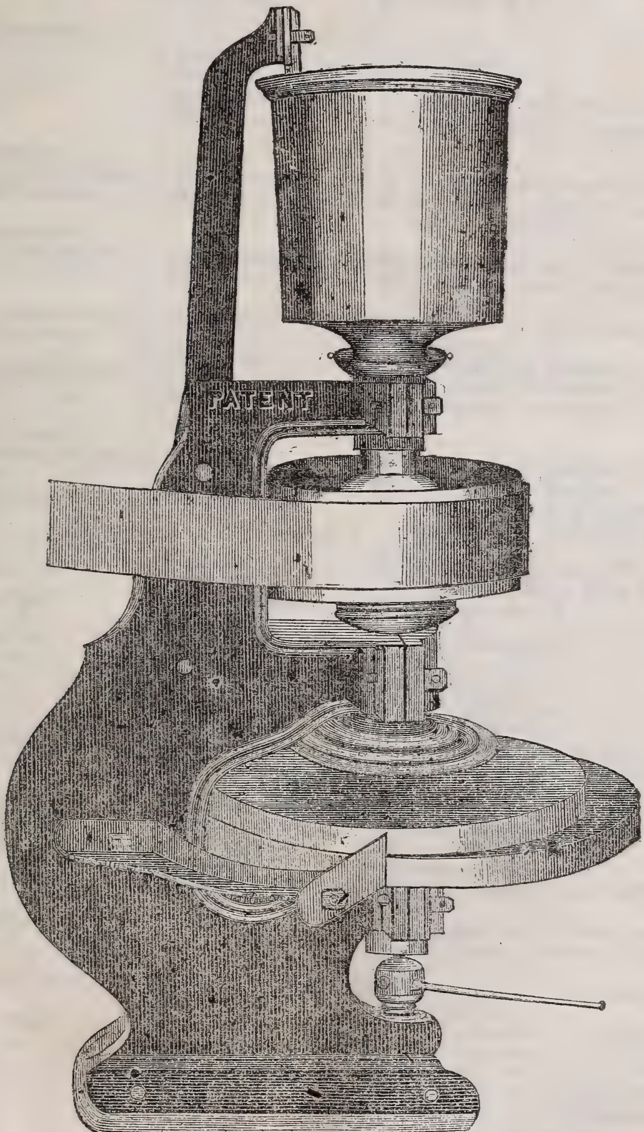
through which the main shaft passes; this is just under the spout of the mill. This reservoir should be filled with tallow, so that it may supply itself. There is also a small hole in the back part of the mill, through which oil can be poured into this reservoir, if requisite. The third reservoir is the step in which the main shaft revolves—that may be filled with oil. The feeding is regulated by a shoe, acting against the tube of the upper plate, which causes the shoe to vibrate; this, with the slide in the hopper, regulates the quantity fed into the mill. Screw holes are made round the rim of the hopper, for the purpose of extending its size to any dimensions required. The mill can be taken apart, cleaned, and the plates changed (if necessary) in a few moments.



Bogardus's eccentric mill, for hulling and grinding dry substances.

For grinding paints and liquid substances.

The mill should run to the right, and make from one hundred and fifty to two hundred revolutions per minute. The belt passes from the back of the mill, running over the front part of the pulley, leaving the front of the mill clear: the scraper must be placed just where the plates coincide with each other, so as to scrape both plates at the same time. The reservoir or step for the under plate should be well supplied with oil. A small syringe



Bogardus's eccentr'c mill, for grinding liquid substances.

may be used for that purpose, or the under plate may be taken out, (this is done in a moment by lowering the screw,) and the reservoir filled with oil. Holes are made in the screw for the purpose of putting in a wrench, by which the screw can be turned backward or forward. Turning the screw to the left will bring the plates together, and cause the mill to grind finer. After running a few hours the plates become faced, and the mill may then be set to grind as fine as desired.

APPENDIX No. 34.

WAGES OF LABOR.

State and county.	Kind of labor.	Price.
MAINE.		
Penobscot and Piscataquis -	Labor on farms -	$12 to $15 per month.
Do do -	Mechanics -	$1 25 to $1 50 per day.
NEW HAMPSHIRE.		
Portsmouth - - -	Husbandmen -	$12 per month.
Do - - -	Mechanics -	$1 per day.
Manchester - - -	Husbandmen -	$12 per month, or 75 cents per day.
Do - - -	Mechanics -	$1 25 per day; same for manufacturers.
VERMONT.		
Washington, Caledonia, Essex, Orleans, and Lamville.	Husbandmen -	75 cents per day; $12 per month.
	Mechanics -	$1 25 per day, including board, equal to 25 cents per day.
MASSACHUSETTS.		
Middlesex and Worcester -	Husbandmen -	$12 to $14 per month; 84 cents per day.
Do do -	Mechanics -	$18 to $26 per month; 87½ cents to $1 50 per day.
Berkshire, Franklin, Hampshire, and Hampden.	Husbandmen -	50 cents per day; $1 in harvest; $11 per month.
Do do -	Mechanics -	$18 per month; $1 per day.
Parts of Essex and Middlesex	Common labor -	$12 per month; 66 cents per day.
Do do -	Mechanics -	$25 per month; $1 per day.
NEW YORK.		
Columbia, Greene, Monroe, and Jefferson.	Husbandmen -	$10 per month; 50 cents per day.
	Mechanics -	$20 per month; $1 per day.
Tompkins, Chemung, & Yates	Husbandmen -	$10 to $11 per month; $120 per annum, including board, estimated at $1 25 per week.
Do do -	Mechanics -	$20 per month in villages; 20 p. ct. less in country; or $1 to $1 25 per day.
Steuben and Allegany -	Husbandmen -	$10 to $11 per month.
Do do -	Mechanics -	$1 25 per day.
Cayuga and Cortland -	Husbandmen -	$8 to $10 per month.
Do do -	Mechanics -	$1 to $1 75 per day.
Rensselaer - - -	Husbandmen -	$8 to $10 per month.
Do - - -	Mechanics -	75 cents to $2 per day.
Do - - -	Factory hands -	50 cents to $1 per day.
Suffolk and Queens - -	Husbandmen -	$10 per month, including board; or 50 cents per day, and board, which is equal to 25 cents.
Do do - -	Mechanics -	$1 25 to $2 per day, and board.
Ulster and Delaware - -	Laborers - -	$10 to $25 per month; $1 per day.
Chautauque - - -	Husbandmen -	$10 per month, and board.
Do - - -	Mechanics -	$15 per month, and board.
Washington and Essex -	Mechanics -	75 cents per day; $10, $12, and $13 per month.
Seneca and Wayne - -	Husbandmen -	$10 per month, or $120 per annum, and board; board estimated at $1 25 per week.
Do do - -	Mechanics -	$20 per month, and board, estimated at $1 50 per week.
Madison and Oswego -	Husbandmen -	$10 to $12 per month; 75 cents per day.
Do do - -	Mechanics -	$15 to $18 per month.
Onondaga - - -	Husbandmen -	$10 per month, and board.
Oneida - - -	Husbandmen -	$10 per month by the year; $15 per month in haying and harvest time; or 50 cents to $1 per day.

WAGES OF LABOR—Continued.

State and county.	Kind of labor.	Price.
NEW YORK—Continued.		
Oneida	Mechanics	$20 per month; 75 cents to $1 25 per day, board included—equal to 25 cents per day.
Herkimer and Montgomery	Husbandmen	$16 per month, exclusive of board; 62½ cents per day.
Do do	Mechanics	87½ cents to $1 25 per day; $16 to $25 per month.
City and county of Albany	Farmers	$10 per month; 62½ cents per day.
Do do	Field laborers	$10 to $12 per month, and boarded; $110 to $125 per year.
Do do	Mechanics	$1 25 to $1 75 per day, exclusive of board; and in the country, 25 cents a day less.
NEW JERSEY.		
Hunterdon, Sommerset, Mercer, and Middlesex.	Husbandmen	75 cents per day; $15 per month, exclusive of board.
Do do	Mechanics	$1 to $1 50 per day, or $200 per year.
PENNSYLVANIA.		
Lancaster, York, and Chester	Husbandmen	$10 per month; 40 to 50 cts. per day.
Do do	Mechanics	$10 to $12 per month; 75 cents to $1 per day.
Bucks and Lehigh	Laborers	$150 to $250 per annum; 50 cents to $1 50 per day.
Philadelphia city and county	Laborers	$1 per day.
Northumberland, Lycoming, Union, and Clinton.	Husbandmen	$25 per month; $1 per day, exclusive of board.
	Mechanics	$30 per month, or $1 25 per day, exclusive of board.
Columbia, Luzerne, and Wyoming.	Laborers	50 cts. per day; $9 to $12 per month.
	Mechanics	$1 per day, and board.
MARYLAND.		
Harford, Cecil, Queen Anne, Kent, and Caroline.	Farm laborers	$8 to $10 per month; 37½ to 50 cents per day.
	Mechanics	$1 to $1 25 per day.
VIRGINIA.		
Halifax, Henry, Patrick, Franklin, and Pittsylvania.	Agricultural	$5 per month.
Campbell, Buckingham, Charlotte, Prince Edward, Cumberland, Fluvanna, and Lunenburg.	Mechanics	$8 to $25 per month; 50 cents to $1 per day.
Kanawha, Jackson, Mason, Cabell, Wayne, Lewis, Braxton, Harrison, Wood, Fayette, Nicholas, Ritchie, Dodridge, Gilmer, Barbour, and Taylor.	Husbandmen	50 cents per day; $10 per month.
	Mechanics	$1 per day; $20 per month.
NORTH CAROLINA.		
Mecklenburg, Lincoln, Iredell, Davie, Rowen, Cabarras, Ashe, Wilkes, Surry, Stokes, Rockingham, and Caswell.	Mechanics	$1 per day.
	Husbandmen	50 to 75 cents per day.
Orange, Person, Granville, Franklin, Warren, and Halifax.	Husbandmen	$7 to $8 per month.
	Mechanics	$16 to $30 per month.
SOUTH CAROLINA.		
Pickens, Anderson, Greenville, and Laurens.	Farm negroes	$5 per month.
	Mechanics	$15 per month.
Chesterfield, Marlborough, Darlington, Marion, Honey, Georgetown, and Williamsburg.	Laborers	28 cts. per day for men; women less; in harvest $1 per day for scythemen.
	Mechanics	$1 to $2 per day.

WAGES OF LABOR—Continued.

State and county.	Kind of labor.	Price.
SOUTH CAROLINA—Continued.		
Spartansburg, Union, York, and Chester.	Laborers -	$6 to $10 per month, and found.
Lancaster, Kershaw, Fairfield, Richland, and Sumpter.	White laborers -	$15 per month; $160 per year.
	Negro laborers -	$8 to $10 per month; $100 per year.
	White mechanics	$25 per month; $250 per year.
	Negro mechanics	$20 per month; $200 per year.
GEORGIA.		
Dade, Walker, Chattooga, Floyd, Paulding, Murray, Gilmer, Cass, Cobb, Cherokee, Forsyth, Gwinnett, and DeKalb.	Husbandmen -	75 cents per day, or $15 per month.
	Mechanics -	Depends on trade.
ALABAMA.		
Covington, Dale, Henry, Coffee, Pike, Barbour, Macon, Montgomery, and Russell.	Laborers -	30 cents per day.
	Mechanics -	$1 50 per day.
Madison, Jackson, Marshall, De Kalb, Blount, and St. Clair.	Laborers -	25 cents per day; $6 per month.
Dallas, Lowndes, Autauga, Perry, Bibb, Jefferson, Shelby, & Coosa.	Laborers -	50 cents per day.
	Mechanics -	$1 to $2 per day.
LOUISIANA.		
St. Martin's, St. Mary, Lafayette, St. Landry, Rapides, Natchitoches, Caddo, Union, Caldwell, Ouachita, Claiborne, Bossier, Sabine, Warren, and Tenas.	Laborers, colored	50 cents per day.
	Mechanics -	$1 50 to $2 per day.
St. Tammany, St. Helena, Livingston, Washington, East and West Baton Rouge, East and West Feliciana, Point Coupee, Iberville, Catahoula, Avoyelles, Concordia, Madison, and Carroll.	Husbandmen -	$12 to $15 per month; $1 to $1 25 per day, and found.
	Mechanics -	$35 to $50 per month.
MISSISSIPPI.		
Average through the State -	Laborers, colored	50 cents per day.
	Laborers, white -	$12 to $15 per month, and found.
	Mechanics -	$30 per month.
TENNESSEE.		
Perry, Henderson, Madison, Carroll, Gibson, Weakly, and Obion.	Husbandmen -	50 cts. per day; $10 to $12 per month.
	Mechanics -	$1 to $1 50 per day; $30 to $40 per month, exclusive of board.
Campbell, Anderson, Morgan, Sevier, Blount, and Monroe.	Husbandmen -	50 cts. per day; $10 to $15 per month.
	Mechanics -	$1 to $1 50 per day; $25 to $30 per month.
KENTUCKY.		
Clay, Estill, Floyd, Harlan, Garrard, Johnson, Knox, Laurel, Letcher, Madison, Owsley, Perry, Pike, Rockcastle, Whitley.	Farmers -	$7 to $10 per month.
	Mechanics -	$15 per month.
Breckenridge, Butler, Christian, Davies, Edmonson, Grayson, Hancock, Henderson, Meade, Muhlenburg, and Ohio.	Laborers -	$80 to $150 per annum, clothed and boarded, or from $8 to $12 per month.
	Mechanics -	Various prices. In shops, by the piece, carpenters furnishing their own tools, $1 to $2 per day.
Bath, Breathett, Carter, Clarke, Fleming, Greenup, Lawrence, Lewis, Montgomery, and Morgan.	Husbandmen -	$10 per month; 50 cents per day.
	Mechanics -	$20 per month; $1 per day.

WAGES OF LABOR—Continued.

State and county.	Kind of labor.	Price.
Ohio.		
Delaware, Marion, and Richland	Husbandmen	$10 per month; 50 cents per day.
	Mechanics	$16 per month.
Franklin, Licking, and Knox	Husbandmen	$10 per month; 50 cents per day.
	Mechanics	$16 to $30 per month.
Jefferson, Carroll, and Columbia	Husbandmen	50 cents per day.
	Mechanics	62½ cents per day.
Fayette, Pickaway, and Fairfield	Husbandmen	$8 per month; 50 cents per day.
	Mechanics	75 cents to $2 per day.
Medina, Lorain, Huron, and Erie	Husbandmen	$17 50 monthly; 80 cents daily, exclusive of board.
	Mechanics	$25 monthly; $1 12½ daily. Mechanics pay more board than laborers.
Mercer, Van Wert, Paulding, Williams, Lucas, Henry, Putnam, Allen, Shelby, and Harden.	Laborers	50 cents per day.
	Mechanics	75 cents per day.
Perry, Morgan, and Washington	Laborers	50 to 62½ cents per day; $10 to $14 per month.
Butler, Preble, and Drake	Laborers	50 cents per day; $10 per month.
Warren, Montgomery, Clinton, and Greene.	Husbandmen	$13 per month, exclusive of board.
	Mechanics	$20 per month, exclusive of board.
Wood, Hancock, Crawford, Wyandot, Seneca, Sandusky, and Ottawa.	Husbandmen	$12 per month, and board.
	Mechanics	$18 per month, and board.
Indiana.		
Dearborn, Ripley, Rush, Switzerland, Decatur, and Franklin.	Husbandmen	50 cts. per day; $9 to $10 per month, including board.
	Mechanics	75 cents to $1 per day, and board.
Jasper, White, Cass, Miami, Fulton, Pulaski, Kosciusko, Marshall, Starke, Elkhart, St. Joseph, Laporte, Porter, Lake, Wabash, and Benton.	Husbandmen	$1 per day in harvest time, and 50 cents per day to common laborer, or $10 per month.
Monroe, Lawrence, Martin, Davies, Knox, Owen, Greene, Sullivan, and Morgan.	Laborers	50 cents per day; $9 per month.
Illinois.		
Lawrence, Richland, Crawford, Jasper, Effingham, Fayette, Montgomery, Christian, Shelby, Moultrie, Coles, Clark, Clay, Edgar, Macon, Piatt, and Dewitt.	Husbandmen	$8 to $10 per month; 37 to 50 cents per day.
	Mechanics	$1 per day.
Lake, McHenry, Boone, Cook, Kane, DeKalb, Dupage Kendall, Grundy, Lasalle, Will, Iroquois, Livingston, McLean, Champaign, Vermillion, and Bureau.	Laborers	75 cents to $1 per day, or $15 to $20 per month.
Alexander, Union, Jackson, Perry, Randolph, Monroe, Washington, St. Clair, Clinton, Bond, and Madison.	Farm labor	$8 to $9 per month.
	Mechanics	$1 to $1 50 per day.
Michigan.		
Macomb, Oakland, Livingston, Ingham, Clinton, Shiawassee, Genesee, Lapeer, St. Clair, Mackinac, Chippewa, Saganaw, Tuscola, Midland, Gladwin, Arenac, Ogenaw, Kanotin, Sanilac, and Huron.	Husbandmen	$10 per month; 50 to 95 cents per day, if they board themselves; $14 to $15 per month, by the year; harvest, $1 per day; board $1 per week.
	Mechanics	$1 25 to $1 50 per day, and board; without board, $2 25 to $2 50, sometimes.

WAGES OF LABOR—Continued.

State and county.	Kind of labor.	Price.
MICHIGAN—Continued.		
Branch, St. Joseph, Cass, Berrien, Van Buren, Kalamazoo, Calhoun, Jackson, Allegan, Barre, Ionia, Eaton, Oceana, Newaygo, Mecosta, Notipeko, Aischum, Manistie, and Katawabet.	Husbandmen -	50 cents to $1 per day.
	Mechanics -	$1 to $1 50 per day.
Monroe, Lenawee, Washtenaw, Wayne, and Hillsdale.	Husbandmen -	50 to 75 cents daily.
	Mechanics -	75 cents to $1 per day; $15 to $20 per month.
The editor of the Michigan Farmer estimates as the average wages of the State:	Husbandmen -	$11 per month; 50 cts. to $1 per day.
	Mechanics -	$20 per month; $1 to $2 per day.
IOWA.		
Average in Territory - -	Laborers -	$12 50 per month.
	Mechanics -	$1 50 to $2 per day.

From the Albany Cultivator.

WAGES OF LABOR.

From an instructive article on the subject of agricultural labor in different countries, its wages, and the comparative condition of the laborer, in the London Mark Lane Express, we condense the following facts: In our estimates we have called the shilling sterling 22 cents, though its value is a trifle less; and the comparison, though instituted with the English laborer, can be easily made with those of this country.

In England, the average rate of agricultural wages for an able man, with a family, is 9 shillings, or $1 98, per week. From this is to be deducted cottage rent at 35 cents per week, leaving $1 63 per week to provide himself with the necessaries of life. In France, a laborer in the same situation receives $1 04 per week; in Prussia, 66 cents; in Germany, $1 02 per week; in Holland and Belgium, $1 20; in Italy and the Austrian States, $1 15. It will be remembered that these averages are those of the common laborer—shepherds, carmen, and mechanics, receiving rather more. The food which the wages named above will purchase in the several countries, is stated in the Express as follows:

In England the laborer can obtain for his 163 cents, or his week's wages, either 39 lbs. of bread, or 11½ lbs. of meat, 7¼ lbs. of butter, 12¾ lbs. of cheese, or 174 lbs. of potatoes.

In France, with his 104 cents, he can buy either 46 lbs. of bread, 13½ lbs. of meat, or 261 lbs. of potatoes.

In Prussia, with his 66 cents per week, the laborer can buy either 36 lbs. of bread, 16 lbs. of meat, or 8¾ lbs. of butter.

In Germany, with 102 cents he obtains either 43½ lbs. of bread, 18 lbs. of meat, 11½ lbs. of butter, 24 lbs. of cheese, or 54 quarts of beer.

In Holland and Belgium, 120 cents will buy either 58 lbs. of bread, 22 lbs. of beef, or 460 lbs. of potatoes.

In Italy and the Austrian States, the laborer, with his 115 cents, can buy

either 50 lbs. of bread, 22 lbs. of beef, 8 lbs. of butter, 8 lbs. of cheese, or 168 lbs. of potatoes.

This table is interesting, as showing not only the prices of labor in the countries named, but also the price of bread, meat, butter, cheese, &c. It is true, the bread is stated by the pound instead of grain by the bushel; but, as the flour of a bushel of wheat, say 40 lbs., will make from 63 to 65 lbs. of bread, an estimate may easily be made of the quantity of wheat or flour a man in any of the countries named would receive for a week's work. The laborer in this country, who receives his bushel of wheat a day, or other articles in proportion, will readily conceive the meagre fare, and slender chance of "laying by anything," which must attend the foreign agricultural laborer. In all these countries it will be seen the value of provisions is at least as great as here, and in some instances much greater. It is only by the comparisons which such authentic statements enable them to make, that the free laborers, the farmers or mechanics of this country, can fully appreciate the advantages of their position.

APPENDIX No. 35.

CURING PROVISIONS, &c.

From the Cultivator.

ON THE CURING OF PROVISIONS FOR THE BRITISH MARKET.

Having obtained the cattle, (averaging between 600 and 800 lbs.,) our next care must be to have them properly killed; and not only the blood of each animal should be well and thoroughly drawn, but every animal should be allowed sufficient time to rest off its journey, say from 24 to 48 hours, according to circumstances, so as to allow the fever consequent on driving any distance to subside before you kill it.

The business of packing is divided into two parts. The first is to cure the meat. The second is to preserve it when cured. In the packing-house the first preparation that should be made for business is the making of the brine in which the beef is to be cured. Neither Kanawha, Zanesville, or Goose creek salt should be allowed to touch your meat, either directly by mixture with other salt, or indirectly through the medium of brine; for so sure as any of these salts are used, so sure will your meat become slimy like fish, and be imperfectly cured. The best salt I know of, for curing, is the Liverpool coarse sack salt, as it is called. The brine should be made for at least ten or fourteen days before it is required; it should be made in large vats or hogsheads, with a sufficient quantity of finely-powdered saltpetre added, to give the beef that red color which so pleases the eye, from long habit; it should be allowed to settle down and refine, and when drawn off into the tubs where the beef is to be cured, it should be clear, and entirely free from any sediment or impurity. The strength should also be tested, which, in the absence of a regular brine tester, may be done accurately enough by placing the half of a hog's head, weighing from seven to eight pounds, in the brine, which must float *perpendicularly*, the snout two inches above the surface, before the brine can be pronounced strong enough.

The next operation in the packing-house is the cutting up of the beef into eight-pound pieces, about which it is impossible to give any specific directions, as the number of pieces must entirely depend on the size, weight, and thickness of the animal. This department of the business must be guided by the hand and eye of the practical tradesman, and directed solely by his good judgment. One thing may here be remarked—that it is always well to leave two prime pieces of every carcass, say off the standing ribs, whole and uncut, to weigh from thirty-two to thirty-eight lbs., and cured in that way, for two reasons: first, when cut up to the proper size after they are cured, it leaves a freshness and bloom on those pieces for the heading, which gives to the purchaser, on opening the tierce for inspection, a certain guarantee that the meat was handled by a tradesman; and, secondly, it will facilitate the scaling of the meat much; as, should thirty-seven pieces be in the scale, wanting one piece more to weigh eight or ten pounds, more or less, that piece can be cut off this larger one to a great nicety, and avoid the delay and trouble of tossing a pile of meat over to hunt up one piece from the many, of the exact weight wanted. In scaling your meat it is not

necessary to put more than the exact weight (304 pounds) in, as beef, when cured and put into tierces, will regain fully 5 per cent. of the 10 per cent. it will have lost in the process of curing.

As your beef is cut, the coarse pieces of the fore-quarter, such as the clods, stickings, and shoulder pieces, should be selected and well rubbed with dry salt, and put into pickling tubs by themselves; the round, rump, and jump pieces of the hind-quarters should in like manner be selected, well rubbed with dry salt, and put into pickling tubs by themselves; and then your prime parts, such as ribs, sirloins, plate, and brisket pieces, should be selected, and put into the pickling tubs by themselves, and *without being rubbed.* Those pieces, being the most tender and least veiny parts of the beef, will cure more easily and quicker than the coarser parts; but after remaining a week in the brine they should be drawn, and if the brine has not sufficiently stricken, then, and not till then, should those pieces be rubbed with dry salt. The coarser pieces should be drawn and examined every fifth day at least; and if the salt should not have sufficiently stricken, and the impurities be not well extracted, then they should be *gently rubbed* a second time, and the air allowed to act for an hour or two at least on the meat and salt, before they are returned into the brine: the whole of the meat in the curing tubs must be well covered with brine, and the air entirely excluded from it. Under a good state of the atmosphere, and with proper handling of the meat, it will be cured and ready to put into the tierces in from fourteen to sixteen days; but of this the practised eye and hand of the tradesman can alone be the judge, for I know of no words to explain the feel and look of meat when cured, or when not sufficiently cured: practice and comparison alone, aided by close observation, is the only certain way of arriving at that judgment.

The propriety of sorting the meat of the three qualities, as pointed out, and having each quality cured separately, I shall endeavor to explain so as to be understood and appreciated by every person possessed of any common sense and experience. First, the finer or middle pieces of every animal, it is well known, are much more easily cured than the coarser pieces of the extremities of either the fore or hind-quarter; hence the propriety of keeping them separate, as, nine times out of ten, it is wholly unnecessary to do more to them (the finer pieces) than simply to place them in the brine, where they will cure without any rubbing, while it is necessary to rub the other pieces once at least, and sometimes oftener, with dry salt, in order to extract thoroughly those impurities which the *lean* of every animal contains in a very much larger proportion than the fatter part of the same animal does; and it is, for the same reason, right and necessary to separate the pieces cut off the extremity of the fore-quarter from those cut off the extremity of the hind-quarter, because the meat of the fore-quarter contains more of those impurities which must be extracted before it is cured, than does the meat of the hind quarter, and consequently the meat of the fore-quarters requires more care and handling, in order to cure it, than does the meat on any other part of the carcass of the animal; hence this classification will enable the curer to give to each sort of meat the required handling necessary for its preservation, without interfering with the other parts, which, if treated in the same way, (I now speak of the finer pieces,) would have their natural juices extracted, become hard, and what is commonly but erroneously called over cured. There is also another reason why this classification should be made—it is this: that it saves much time and labor, when the

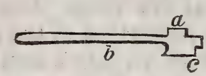
meat is selecting for the scale, by having each quality in separate bulk: the selector has but to go to either in order to lay his hand at once upon the particular piece he wants, without losing time or wasting labor in tossing over a pile of meat promiscuously cured.

When your meat is cured, the next process is the packing it away for preservation into the tierces, about which I deem it unnecessary to say anything; because, when the meat is selected and scaled, the packing it is a mere mechanical process, in which a man can alone become a proficient by practice and experience. It may be well enough to remark, that when your meat is taken out of the curing tubs it should be washed, and rid of the impurities extracted by the salt, and generally in a greater or less degree deposited on the surface, and which can be best and most easily done with the aid of water and a good hickory broom; the packer should always have by him a knife, and whenever he observes an incrustation of those impurities on the meat, which the washing had not taken off, he should use his knife to scrape it off; and if scraping does not effect it, he should cut it off.

When your tierces are packed, they must then be headed and thoroughly driven down in their *wooden hoops*, rolled by, and each tierce have its bung hole bored, and then brined with pure, clean brine, made and tested in the way before described, except that *no saltpetre* should be put in it. It is of the utmost importance that this brine should be made several days before, in order that not only the impurities of the salt, but those of the water also, should have time to settle down into a sediment, and this sediment should not be disturbed when the brine is drawn off. The want of this precaution has been the cause of much complaint and injury to the meat when exposed for sale, from the fact that when the brine was put on without first being allowed to clear itself, the impurities of both the salt and the water settled upon the meat, and made it both slimy and dirty. The tierces should remain at least fourteen days in this state, with the bungs open, and whatever the casks may have absorbed of the brine should be replenished once, if not twice, every day, and this continued until the casks will absorb no more, and the brine remains as stationary and undiminished, when filled, as though it stood in a glass bottle. The necessity for this precaution is obvious: first, if your staves are not in this way allowed to become saturated with brine, and the brine replenished before the casks are finally coopered and shipped, you can have no guarantee for your casks not leaking on the voyage; and, secondly, should this absorption be allowed to take place on the voyage, your tierces in a short time will become half empty of brine; and wherever your meat then comes in contact with the stave, it will extract from the wood its coloring matter—it will become stained and discolored, and, for the want of brine, the meat will become hard and rancid, and perhaps mouldy too. Your tierces, after standing at least fourteen days, will take no more brine. They are then ready for the bungs, which should be put in with a coarse cloth around them, and tightly driven; over each bung a piece of tin should be nailed on, but great care must be observed that the tacks with which it is fastened are so short as not to go through the stave; as, if they do, a leakage will take place that may do much harm.

Then comes the finishing stroke to the whole—the putting on of your iron hoops, and the final coopering of your tierce. As few coopers are in the habit of doing such work in the United States, I shall explain the process, so that all may understand, and perform it, if they will. In the first place,

care should be taken to clear your house of all salt and brine, in order that the hoop-iron may be keep as free from it as possible, to prevent rust and corroding. The tierce up-ended, the cooper takes off the three first wooden chime hoops; he then takes his hoop-iron and bends it around the place of the *first* hoop, and takes its accurate measure; there, he then cuts it to the length, and rivets it, which can only be well done on the face of a small anvil, or on the side of a metal half-hundred weight; he then puts this hoop on, (having eased it, by a few blows on the inside of one edge, to the shape of the cask,) and drives it to the berth of the *second* wooden hoop, leaving room for a wooden guard hoop on the outer edge of the chime; he then strips that end of the tierce of all the remainder of its wooden hoops, and takes his hoop-iron and measures around the berth of the *third* wooden bulge hoop, cuts, rivets, and shapes it, and then puts it on and drives it down to the place of the *second* bulge hoop; this done, he then puts on his wooden guard bulge hoop, which passes over the iron one, and drives it to its place, and then drives on the remainder of his wooden hoops, finishing with a guard chime hoop outside the iron one, and so proceeds on until the whole is coopered. It is necessary here to remark, that no iron driver, used perpendicularly, as coopers use their wooden drivers on wooden hoops, will ever drive an iron hoop to its place. There is a proper driver, without which the hoops cannot be driven. It is thus:



b, the handle; *a*, the head on which the blow is given; and *c*, the bite which catches the edge of the hoop: this, used with a 7-pound hammer to strike with, will drive any iron hoop to its place; but without it, the hoop cannot be stretched and driven, and consequently must remain imperfect.

AN APPRENTICED PACKER.

LOUISVILLE, KY., *November* 4, 1845.

SALTING BEEF AND PORK.

Mr. R. H. Ostrander, of Glenville, informs us that he has for several years pursued the following method with success: "In packing down pork, I sprinkle in four quarts of rock salt to a barrel, then make a pickle of warm water sufficient to cover all the meat, as strong as can be made with salt, and, when cold, pour it on; when the pickle becomes much colored with the blood of the meat, draw it off, boil it, take off the scum till it becomes clean, and apply it again; in this way pork will keep sweet throughout the ensuing summer, and will be free of rust.

"In salting beef, take four quarts of rock salt, pounded fine, eight ounces of saltpetre, and five pounds of brown sugar; mix them well together, and with these ingredients pack the meat down very closely, so as that they will of themselves cover the whole with brine. The next spring, draw off the brine, clarify it as before mentioned, adding a little salt to it, and apply it again, and the beef will keep very sweet and fine-tasted during the whole summer following."

Mr. J. R. Fuller, of Kent, Connecticut, says: "In looking over the Oc-

tober number of the Cultivator, I saw some remarks on the subject of preserving pork, with a request that if any one had practised the same method, to inform you of the result. I have for more than twenty years, with very few exceptions, cut and packed my pork and hams the evening after butchering, and always pour on the brine boiling hot, the same evening, or the next morning. The barrel should be left open until the brine gets cold. I have never known any one that has tried that method, who was not satisfied with the result. I can, therefore, with the fullest confidence recommend that method."

From the New York Farmer.

At a meeting of the Farmers' Club, the president, Dr. Rhinelander, read the following from the practice at Cincinnati: "To one barrel of 150 pounds, four quarts of salt, two pounds of sugar, and one pound of saltpetre, pounded fine, and rolled together until they are thoroughly mixed; each ham is thoroughly rubbed with that compound over the entire surface, and as far around the bone as can be reached; the hams are then placed in a barrel for two weeks; then put in six quarts of wood ashes, with ten gallons of water, and boil about two hours; let stand until settled, at the same time making a strong brine; nine gallons of brine to one gallon of lye; pack in this, and let them lie four weeks."

Mr. Woodhull.—To a barrel of hams, one gallon of molasses, two ounces of saltpetre, and cover with a strong brine; take them up in ten or twelve days, and repack them.

Mr. Walters.—For every one hundred of meat, two quarts of molasses and four ounces of saltpetre, with a strong brine.

From the American Agriculturist.

PACKING PROVISIONS FOR THE ENGLISH MARKET.

Mr. Rotch, writing us from London, says:

"The early attention you asked of your readers to the English mode of putting up provisions begins already to manifest itself in the very improved manner in which they are now brought to this market, and the improved prices they command.

"Bacon for the London market must not be enveloped, as for the country consumption, with a thick coat of fat; on the contrary, it should have but little fat, and its muscle or lean parts must be well marbled with it. However, as yet, bacon is not cured to any extent in the northern States. Tongues have been sent here, but have been so badly trimmed, so bloody, and so slovenly put up, that they did not sell for more than half price. Properly put up, they would have sold at from 4*s.* to 4*s.* 6*d.* apiece; for here they are sold at 4*s.* 6*d.* to 5*s.* 6*d.*, when cured as they should be.

From the Dollar Farmer.

CURING HAMS.

We republish the following method of curing hams. There is none better.

For every one hundred pounds of meat, take five pints of good molasses, (or five pounds of brown sugar,) five ounces saltpetre, and eight pounds rock salt; add three gallons of water, and boil the ingredients over a gentle fire, skimming off the froth or scum as it rises. Continue the boiling till the salt, &c., is dissolved. Have the hams, nicely cut and trimmed, packed in casks with the shank end down, as the pickle will thus strike in better. When the pickle, prepared as above, is sufficiently cool, pour it over the hams. They may lie in pickle from two to six weeks, according to the size of the pieces or the state of the weather—more time being required in cold than in warm weather. Beef or mutton hams, or tongues intended for smoking and drying, may be cured according to this mode, and will be found excellent.

The Albany Cultivator adds the following:

In that excellent and agreeable work entitled "Farming for Ladies," we find the following directions for preparing the celebrated "Hambro pickle," which is said to be equally applicable to beef, pork, tongues, &c. "To each gallon of water, put one pound and a half of common salt, a quarter of a pound of coarse brown sugar, and one ounce of saltpetre; boiled, and to be carefully skimmed. After standing in a proper vessel until quite cool, the meat may be immersed, and will be fit for use in ten days and improve for months; but it must be carefully kept pressed down by means of a cover, and a clean heavy stone. The pickle must be watched, and, when any scum begins to rise, the meat must be taken out and the liquor reboiled, and skimmed and cooled as before; at the same time half a pound more salt must be added, but no raw salt is to be applied at any time. The meat is to be returned when the pickle is quite cold, say after ten or twelve hours. Tongues will require a month at least, and are improved by the addition of an ounce of bay salt added to the above. One clove of garlic, half an ounce of alspice, and as much whole pepper, boiled with the ingredients, much improve it."

From the American Agriculturist.

DAVISON'S INVENTION FOR CURING PROVISIONS.

The whole apparatus is perfectly simple. It consists of a large cylinder, made *air-tight.* It has a mouth-piece, through which the meat is put into the cylinder. On this mouth-piece is fitted a lid, with its surface so adapted to the mouth-piece that no air can pass. Strong screws bind it close to the mouth-piece. On the lid are two vents, with screws to open and close them. This cylinder, mouth-piece, and lid are made of the best of iron, with a thickness proportional to their size.

There is also a large vat to hold brine. This is made of wood, and is elevated above the cylinder, and connected with it by a pipe. Through the pipe the brine passes from the vat to the cylinder. There is a lifting-pump attached to the cylinder. By it the brine is pumped from the cylinder into the vat.

The meat, being first cut, is placed in the cylinder and the brine admitted. When the cylinder is filled with the brine, the lid is closed down on the mouth-piece and screwed fast. The pump is then put into action, and the brine carried back to the vat. When the brine is all removed from the cylinder, the meat is in a vacuum; this is obvious, for the brine had of

course expelled the air; the cylinder and closed lid being air-tight, did not permit the air to return when the brine was withdrawn. The meat being in a vacuum, parts with all the blood, air, and gases which may be contained within it: these escape into the vacuum of the cylinder. The brine is now again introduced, and when the meat is covered, the air-vents in the lid are opened, and the brine drives out all the air and gases which had escaped from the meat. When the cylinder is full of brine, the air vents are closed, and the brine is pumped into the vat, and the meats are again in vacuum. Again, blood, air, and gases escape into the vacuum. The brine is again introduced, and the meat covered; the air-vents are then opened, and the air and gases escape from the cylinder, and the cylinder is filled with brine. The brine is withdrawn and returned again and again until the operation is completed. The interval of withdrawing and returning is short at first; but when the blood, air, and gases are expelled from the meat, the brine is allowed to remain on the meat for some hours—say four to eight. After the blood, air, and gases are expelled, and the meat has remained in the brine for six or eight hours, it is cured. The whole process will require about twelve hours.

The principle on which the method acts is that of a pressure upon the meat in a vacuum. In its ordinary condition the meat is filled with blood, air, and gases; when immersed in brine, in the ordinary process, these, by their resisting power, prevent the brine from entering the meat; the blood has an affinity with the brine, and leaves the meat to unite with it. The pressure of the water and its specific gravity being greater than that of the air and gases, the air and gases rise to the surface and escape, and the brine takes their place. To do this, however, takes time, and about six weeks are found necessary to accomplish it. When, however, the meat is in a vacuum, the blood, air, and gases *escape at once;* being escaped, the brine exerts its pressure, and the meat is charged at once. This pressure, in the ordinary method of curing, is nothing more than that which arises from the weight and pressure of the quantity of brine necessary to cover the meat. In the cylinder, the meat, when the blood, air, and gases have been separated from it in the vacuum, can be subjected to an illimitable amount of pressure. To do this, nothing more is necessary than the elevation of the vat. Connected as is the vat, by a pipe, to the cylinder, the pressure is in proportion to the elevation of the vat. By means of the vacuum the meat is freed from all the means of resistance to the entrance of the brine; and the pressure of the brine may be carried to any extent that the meat will bear without collapsing. When in vacuum, it is swollen, its fibre distended and pores open, and it readily admits the brine, even at the simple pressure of the mere quantity of brine which the cylinder will hold. In this matter, experience has taught that the pressure of a single atmosphere is the most effective; a greater one tends to close the pores of the vacated meat, and a triple atmospheric pressure completely closes them, to the exclusion of the brine. The whole secret of the action of this method is, that the vacuum fits the meat at once to admit the brine, and the pressure, if not too great, at once forces the brine into the vacated pores; and this done, the meat is cured. By the use of the vacuum, the natural process is shortened from weeks to hours, and the meat is cured *at least as perfectly*—indeed, far more perfectly.

The advantage of a *rapid* curing of meat in a perfect manner is obvious

to every one. But there are numerous advantages besides. Let me enumerate them:

All meats, salted and cured in the ordinary method, require two packings to pass inspection, and for family use. When the meat is cured, which will be at the end of six weeks or two months, the brine is bloody and foul. In the large packing and inspection establishments the meat is repacked, and the first brine is thrown away. With the vacuum process, the meat, when cured, at the end of twelve hours is free from blood, and ready to receive its final packing, fit to pass inspection, or keeping for family use. In the process of curing, pork increases in weight ten or eleven per cent. In the ordinary process, two months are necessary to gain this; and, of course, the interest, storing, and insurance for that period are lost to somebody. In the vacuum process the meat is cured in twelve hours, and the ten per cent. gain is *obtained at once*, and there is no loss of time, interest, storage, or insurance. In the ordinary method the packer cannot sell profitably until after two packings and two months of time; in the vacuum process he may sell in one day, reaping the gain of the increase.

The longer the meat is in curing, the more the natural juices are extracted by the brine. Hence, when the meat is cured equally well as to its being saved, its quality will be better in the short process, for its juices are not lost in the brine.

These advantages apply to all seasons of the year; and by the vacuum process there is a great gain, even in the winter, when meat can be cured by the ordinary process. But there is yet another advantage, and it is this:

Meat, by the vacuum process, may be cured in the summer as well and as perfectly and safely as in winter; once in the cylinder, it is safe. The cylinder will make it so at once, under any circumstances; but, if necessary, the cylinder may be enclosed in a wooden box, (a non-conductor,) and the space between the case and cylinder filled with powdered charcoal. This at once makes a refrigerator, and, with the brine, a temperature approaching freezing point may be maintained during the whole time of curing.

In the west, less capital for the purchase of meat will be necessary if the vacuum process be adopted; for time, interest, storage, and insurance will be saved. But to the west it will give yet another advantage: it will enable them to commence packing earlier. Not unusual is it for them, at Cincinnati and St. Louis, to be closed up in December with ice, and a stop put to shipment. If packing can commence in October, the loss of cold weather in feeding and the staying power of ice will be obviated. A hog or a beeve is fatted more easily in warm than in cold weather. But neither can be killed and cured in warm weather by the ordinary process: by the vacuum process they may. To pack in the ordinary way you must feed longer, and that even with a scarcity of food, to get to the cold weather, that you may safely cure; and by no means can you meet a present demand or a rising market. By the vacuum process you obviate long feeding, warm weather, (and that may occur even at mid-winter to spoil meat cured in the ordinary mode,) and you may meet a present demand or a rising market, without loss of interest, storage, or insurance. It may be objected that there is an expense in the vacuum process not incurred in the ordinary one. In the ordinary process you cure and wait two months, and then repack for inspection or to keep for family use. In the vacuum process you cure and pack, and are done; and the two packings of the

ordinary mode are more expensive than the curing and packing of the vacuum process. Hence there is economy in capital and outlay, in time and expense subsequent to the first packing. To this is to be added, that the meat is better on account of the retention of its natural juices in a greater degree. Here all comparison between the two methods ends. The advantages of the vacuum process, besides, are all its own.

Hitherto, when meat got skippered or tainted it was lost; now, it can be saved. If skippered when placed in a vacuum in the cylinder, the skippers come to the surface of the meat, and perish for want of air. The meat is then taken from the cylinder, the skippers removed, and the meat returned to the cylinder and again charged with pickle, and is again perfect.

If meat be tainted, it is placed in the cylinder and charged with a weak solution of lime: taken out, dried, and returned to the cylinder, and again charged with pickle; and then it is difficult to distinguish it from sound meat.

Hams and bacon, old, blackened, and spoiled in appearance, will not take in pickle by immersion: subjected to the vacuum process, they may, and in a few hours be restored to fresh appearance, and after smoking be equal to new ones.

Meat just killed and *warm* may be put, in mid summer, into the cylinder, and cured in twelve hours perfectly. By steeping, it cannot be cured at all in warm weather; in vacuum, it may be at all seasons.

Beef cured in the vacuum is done and packed in a day, and has gained its full increase. Cured by steeping, it at once loses five per cent., and takes months to regain its loss and add the usual gain arising from packing.

In hot climates, meat cannot be cured by steeping at any season; by the vacuum it can in any climate, at all seasons.

In ordinary packing, sugar, spices, or acid may be added to the brine; but in the vacuum process they will be more perfectly taken up, and the meat more highly flavored.

The vacuum process is applicable to all kinds of meats; and all kinds of fluids may be infused into meats by it. A variety of antiseptics besides salt will preserve, if they can be injected into the meat; but before the meat could take them by steeping, it would be spoiled in any weather but the coldest, and in the coldest would be stale first. By the vacuum these may be injected at once, and the meat flavored by these peculiarly preservative fluids.

To the west it offers great facilities and economies, as the west is now the great meat grower and packer.

But this invention is truly a great boon to the people of the south. They now bring their pork and beef from the west. Hereafter they may cure it for themselves. Now, they cannot, with a certainty of keeping, even in winter. With Mr. Davison's process they may cure at all seasons. Hereafter they may cure with safety and economy. They may thus become not only their own pork and beef growers, but they may add pork and beef to their exports. Indeed, in time, it may fairly be predicted that the region of country on the gulf of Mexico will be the only country that can export pork and beef profitably. Her climate will grow it without expense, for her pastures are ever green; and her fields may ever be filled with pork-fattening esculents. In no region does a good hog do better than in a

warm one. In the cotton and sugar region every planter may himself make all his bacon, for he is now able to cure it.

To families of farmers, living in the country, it offers the means of having fresh meat during the summer without waste; for, what cannot be eaten fresh can be packed, and will be the best pickled meat, as it will be recently cured.

There is yet another view in which this invention will wonderfully serve farmers and planters. By it they can impregnate wood with salt, and the wood will be indestructible; or may turn it to stone, measurably, and it shall yet be flexible, and can never rot, and only be lost by wear. By it shingles for houses, and posts for fences, may be made indestructible. To do this it is only necessary to impregnate them with brine thoroughly. But it may be carried still further, and the wood turned wholly to stone; and thus: The wood is first charged with salt, then with sulphate of iron, and dried, then charged with a solution of muriate of lime; this latter, coming in contact with the sulphate of iron, decomposes the wood and forms an insoluble compound—sulphate of lime, or gypsum. The wood then becomes stone, and yet retains toughness.

The chief merit of this apparatus is its extreme simplicity and the economy with which it operates. The solution of salt, or brine, which is used in most cases, both for curing meat and wood, is not costly. No more of it is expended than the meat or wood takes up; the balance is returned to the cistern, and serves for another or other operations. If a little sweetening matter or spices be added, the cost is not greatly increased; and for the other operations contemplated upon wood the same applies, for most of the required solutions are made from the cheapest ingredients. The apparatus, constructed of metal, will last for centuries. If it should get out of order, the rudest mechanic in the country can put it to rights. A boy of fourteen years of age can work it as well as a man. In fine, although many of the principles involved are not new ones, yet it so happens that no other apparatus heretofore invented rendered them of public utility, on account of great expense, while, by this one, they can be made *practically*, *cheaply useful*.

A. S.

NEW YORK, *December* 16, 1845.

From the American Agriculturist.

DAVISON'S PATENT PROCESS FOR CURING MEAT.

The undersigned is authorized by the patentees to sell patents for the using and sale of Davison's apparatus for curing meats, and preserving timber, and also for the sale of rights for States. By this process, all kinds of meat can be perfectly cured in twelve hours, and in warm weather as well as cold. It leaves all the juices in the meat, and of course it makes a better article. Bacon cured in it may be put to smoke in two days. It is just such an article as every planter in the south should have. Applications for rights and single machines may be made to the subscriber. The price of the machines is from $75 to $300, according to size.

APPENDIX No. 37.

MR. FLEISCHMANN'S LETTER.

VIENNA, *September* 20, 1845.

DEAR SIR: In my last from Berlin, I mentioned that I intended to assist the convention of German agriculturists, at Breslau.

I arrived a day before the commencement, entered my name as a member, and assisted the opening of the first meeting. There were upwards of a thousand agriculturists from the different parts of Germany; each State was represented by some deputies from their respective monarchs, and it was highly interesting to hear the debates on the different subjects of agriculture, in which the princes, counts, &c., joined in with the rest; and they took as much interest and evinced as much knowledge as most of the ordinary farmers themselves.

These conventions, which have been held for nine years, (every year at another city of Germany,) have already had a very beneficial influence; the farmer sees that his occupation is not only respectable, but worthy, and important to the attention of every member of the society.

The questions were debated in separate sections, and to me that of wool was of the highest interest. Silesia has now the reputation of raising the finest wool. Samples of wool were exhibited in a large room, from all parts of Germany, also Hungary, Russia, New Holland, and some of the alpaca. I spent most all my time in that room, to examine into the different characters of wool from the different countries, and especially those which resemble ours the most in regard to climate and treatment.

I obtained a collection of wool which can nowhere be got except at such an occasion, and I was told this was the only exhibition of that kind ever seen.

A new species of potatoes was exhibited, of which I obtained some bulbs. It is an early potato, and ripens the middle of June; it is different from any I ever saw; they look like cocoons, of the size of an egg.

The samples of flax and hemp were beautiful, and Silesia tries to sustain its reputation as a flax-growing country; it was its staple article for centuries, and it will ever be such.

I had various conversations with the principal flax and hemp-growers in regard to the treatment, and hope to lay before you such communications as will be interesting and useful for our country.

I saw several new machines for breaking hemp, one of which proved very useful and practical, of which I made a sketch.

The citizens of Breslau (a city of 100,000 inhabitants) exerted themselves to make their guests during the time as pleasant as possible. All the different clubs opened their establishments for us. A rich count, of the name of *Henkel*, gave a splendid ball and supper at his palace, where all the beauty and grandeur of the country around, and of the city, were assembled; diamonds, orders, ribands, stars, medals, &c., and all kinds of distinctions of honor, were massed together.

The city struck a medal in honor of the occasion, one of which I shall bring you. The King gave a great dinner at the chateau; and on Monday there

was a cattle show, distribution of prizes for the best breed of horses, cows, and sheep, a horse race, and a great procession, in which the different agricultural occupations were exhibited—the country people all in their national costume; and, after all was over, and the assembly of more than 100,000 people had dispersed, the city gave us (in a beautifully decorated and illuminated garden) a supper, and closed with splendid fire-works. Saturday evening a piece was performed in the theatre, written for the occasion by a poet of Breslau, in which Ceres shows the importance and beauty of agricultural occupation.

The agricultural implements cannot be compared with those of America; they are clumsy, and against all rules of mechanical science: here lies the fault of Germany. Science is taught at the universities, with great care and perfection, but the practical results have not yet found their way down to the common man. The system of common school education throughout Germany is excellent, but the preparatory schools for the different branches of occupation, as trade, commerce, &c., are wanting.

* * * * * * * *

I recommend myself to your friendship, and remain your obedient servant,

CH. L. FLEISCHMANN.

Hon. E. Burke.

P. S.—I called on the director of the Imperial Polytechnical School, Mr. Prechtl, who very kindly initiated me in all the details of the Austrian patent laws, which are the most liberal I have learned yet. I shall have all the laws, information, and forms of their patents, which will be at your command. He also laid before me the yearly publication of expired patents, in which an extract of the specification, or, where the specification is of importance, the whole is given, with drawings; there are only three volumes now, and I consider it very important for our office. I intend to procure it, and all such works as I find interesting, and send them on to Washington.

[Rules of German convention of farmers, and subjects for discussion from London Gardeners' Chronicle, omitted for want of room.]

APPENDIX No. 38.

CHARCOAL ROAD.

The process of making such a road is described by a writer in the Cleveland Herald, as follows:

"Timber from six to eighteen inches through is cut twenty-four feet long, and piled up lengthwise in the centre of the road about five feet high, being nine feet wide at the bottom and two at the top, and then covered with straw and earth in the manner of coal-pits. The earth required to cover the pile, taken from either side, leaves two good sized ditches, and the timber, although not split, is easily charred; and, when charred, the earth is removed to the side of the ditches, the coal raked down, to a width of fifteen feet, leaving it two feet thick at the centre and one at the sides, and the road is completed."

A road of this kind is now being made in the Cotton Wood swamp near Blissfield, in Michigan. From the writer above quoted we learn that about seventy roods are completed, twenty of which have been used for the last seven months, and the balance for three months; and as it is on the great thoroughfare west, and as, in addition, on an average, sixteen heavy loaded teams to and from an ashery pass over it daily, it has been very well tried during the winter and spring, and yet there is no appearance of ruts, but it presents an even, hard surface.

The company making the road pay the contractors at the rate of $660 a mile. The road is said to become very compact, and to be free from mud or dust. Hon. Elisha Whittlesey, and Mr. Newton, an engineer who inspected the Blissfield road above mentioned, state that they passed over it the morning after a rain.

"At each end of the different sections of the coal road the mud on the causeway was felloe deep where there was that depth of earth, and nearly or quite half-axletree deep where the logs were broken; when, on the coal road, there was not the least standing, and the impress of the feet of a horse passing rapidly over it was like that made on hard washed sand, as the surf recedes, on the shore of the lake. The water is not drained from the ditches, and yet there are no ruts or inequalities in the surface of the coal road, except what is produced by more compact packing on the line of travel. We think it is probable that coal will fully compensate for the deficiency of limestone and gravel in many sections of the west, and, where a road is to be constructed through forest land, that coal may be used at a fourth of the expense of limestone."

APPENDIX No. 39.

NATIONAL CONVENTION OF FARMERS AND SILK CULTURISTS.

Mr. Robinson, of Indiana, from the committee to prepare an address to the people of the United States, reported that they had agreed upon the following address, which they now submitted to the convention for its consideration:

To the friends of improvement in the science of agriculture, horticulture, and silk culture, in the United States:

The convention of delegates representing these important interests, now holding their third annual meeting under the call of the American Institute of New York, address their brethren who have not the good fortune to be with us upon this occasion, to congratulate them upon the fact that the course of improvement in the cultivation of the earth is still onward. And why should it not be so? We possess a country of rich soil, and a climate reaching from the line of tropical plants to that of a region so cold that man must resort to other means for support besides cultivating the earth.

But, with all our advantages of soil and climate, there appears to be a conceded opinion among all the cultivators of the earth, that they do not enjoy the advantages and comforts enjoyed by other classes of society, who never knew what it was to earn their bread by the sweat of the brow. The cotton planter of Mississippi tells us that he cannot support his laborers upon the product of his plantation, because the price of cotton is too low. But would not a more careful management, and a more diversified culture, obviate his difficulty? He is not required to raise cotton alone—his soil and climate are equally adapted to raising wool; tobacco, also, of the finest quality, will grow where cotton will, and no part of the country can excel this section of the Union for raising fruit. The remedy for over-production and low prices of cotton must be a more diversified culture and greater amount of home productions of all the things for which the cotton region is now tributary to the north. We are gratified to learn that the cultivators of sugar do not complain of their present prospects in all the cane-growing region. We do not hear of any extended operation in the manufacture of sugar from cornstalks.

We regret to learn that throughout several of the southern corn-growing States there is a great failure in the crop, owing to the excessive drought which has prevailed in nearly all parts of the United States during the last summer. For this we cannot suggest any remedy, except that, in all our cultivation, we aim to guard against a state of drought which prevails through all our country, to a far greater extent than the contrary during the crop-growing season. We hear of the same drought prevailing in Ohio, to so great a degree that there is not foliage enough to carry the stock through the winter in the northern part of the State. The soil here is a stiff clay, and, from the personal observation of one of the committee during the last summer, he is convinced that the use of the sub-soil plough upon

this soil would greatly tend to lessen the tendency to loss of crops from drought.

From Maine we hear of an almost total loss of the staple crop of our friends in that cold region of the Union, from that mysterious and very serious disease among the potatoes, that has not very inaptly been likened to the cholera in its ravages. It is of the utmost importance that all the information tending to cure this hitherto incurable disease should be concentrated, and for that purpose we recommend that the members of the corresponding committee in the several States, which have been appointed at this meeting, communicate to the committee in this city all valuable facts that they can obtain upon this subject.

From the southern part of the wheat-growing region we hear great complaints of the ravages of the weevil. The convention are anxious to gather information upon this subject. We learn that the destruction of the crop from this cause has been prevented in some regions by mixing about one bushel of lime with one hundred bushels of wheat, in the barn, which has to be winnowed out before grinding. Unless some discovery is soon made to obviate the difficulty of the weevil, the cultivation of wheat in the southern parts of Indiana and Illinois, and in all States south of that, must be abandoned.

The most abundant crop of all that we are informed of, during the present year, is that of peaches in the State of Delaware. So great has the crop been, that we hear of one individual chartering a large steamboat to take the fruit of his own and son's farms to market.

The production of wheat the past year, generally speaking, has been over an average crop, and of excellent quality.

The crop of corn in the great corn region of the west seems to be very abundant.

We also have evidence before us that tends to show that the culture of silk is now beginning to be adopted in families, where we think it may be profitably confined, while it is abandoned as unprofitable by joint stock companies.

We are pleased to learn that wool-growing is found to be profitable in all parts of the United States, and that there is an immense field open for the extension of wool growing upon the great prairies of the west, and that the business would be more profitable even than that of cotton in the southern States.

But, notwithstanding all the bountiful productions of some crops, there is evidently a general depression of the agricultural class pervading the whole country.

It is one of the objects of this convention to seek out a way by which the condition and character of the cultivators of the American soil can be elevated and improved. For this purpose we recommend the extensive formations of farmers' clubs, and largely increased reading of agricultural papers and other valuable publications, which have, of late years, been so extensively multipled for the farmer's use. We also recommend most earnestly to all our common as well as higher schools to adopt, as an unvarying branch of education, subjects calculated to impress upon the minds of the young the necessity of applying science to the cultivation of the earth, and that it is the original and most honorable, as well as the most happy and healthy of all employments. We also recommend that an earnest appeal be made to Congress to adopt at once the recommendation of our father, Wash-

ington, and establish a "Home Department" for the encouragement and support of the agricultural interests of our country. In aid of these views we offer the following resolutions:

Resolved, That the American Institute, by whose co-operation this convention was called, be requested to continue their noble efforts in the cause of agricultural improvement, by adopting measures to have this matter brought before the next meeting of Congress.

Resolved, That the members of this convention will look upon it as an act of great respect to this body, if the American Institute will again take it upon themselves to publish to the world the proceedings and views of the convention.

Resolved, That the alarming situation of a great part of the world at this time, in consequence of the disease called the rot in potatoes, requires the most active, prompt, and untiring exertions of all the producers of this most important production, to subdue, if possible, the frightful ravages of this disease, and to prove, by successful experiment, that the country which originally produced this invaluable root, one of the most sustaining sources of subsistence to the population of Europe as well as our own country, can provide a remedy to prevent its extinction.

SOLON ROBINSON,
HENRY MEIGS,
C. C. HAVENS,
Committee.

APPENDIX No. 40.

GENERAL ABSTRACT OF THE QUANTITIES, VALUE, &c., OF MANUFACTURES AND AGRICULTURAL PRODUCE MANUFACTURED AND PRODUCED IN THE STATE OF MASSACHUSETTS DURING THE YEAR ENDING APRIL, 1845.

Manufactures of cotton.—Number of mills, 302; number of spindles, 817,483; pounds of cotton consumed, 56,901,954: yards of cotton cloth manufactured, 175,682,919; value of cotton cloth, $11,164,212: pounds of cotton yarn made into cloth, 1,360,026; value of cotton yarn, $284,061: pounds of cotton thread, 443,214; value of cotton thread, $269,903: pounds of cotton batting, 2,506,565; value of cotton batting, $158,014: pounds of pelisse wadding, 176,200; value of pelisse wadding, $44,000: yards of cotton flannel, 2,718,695; value of cotton flannel, $273,259: capital invested in the manufacture of cotton, $17,739,000: males employed, 6,303; females employed, 14,407.

Calico.—Calico manufactories, 14; yards of calico printed, 40,855,810; value of calico, $4,779,817: yards of goods bleached and colored in calico factories, and not printed, 880,196; value of the bleached goods and colored, $92,000: capital invested, $1,401,500: males employed, 1,887; females employed, 166.

Bleaching and coloring.—Establishments for bleaching and coloring cotton goods, and not connected with calico establishments, 9; yards of goods bleached or colored, 22,291,008; value of goods bleached or colored, $2,074,000: capital invested, $200,500; hands employed 211.

Woolen.—Woolen mills, 178; sets of woolen machinery, 514; pounds of wool consumed, 15,387,448; yards of broadcloth, 1,022,359; value of broadcloth, $2,157,392: yards of cassimere, 2,451,458; value of cassimere, $2,416,818: yards of satinett, 3,558,720; value of satinett, $1,907,327: yards of Kentucky jeans, 1,652,345; value of Kentucky jeans, $449,685: yards of flannel or blanketing, 4,490,937; value of flannel or blanketing, $1,284,967: pounds of woolen yarn not made into cloth, 256,205; value of woolen yarn, $99,689: value of goods not specified, $561,600: capital invested, $5,604,002: males employed, 3,901; females employed, 3,471.

Carpeting.—Mills, 17; pounds of cotton consumed, 150,000; pounds of wool consumed, 1,786,238; yards of carpeting, 1,158,958; value of carpeting, $834,322: capital invested, $488,000: males employed, 715; females employed, 319.

Worsted.—Establishments for the manufacture of worsted goods, or goods of which worsted is a component part, 10; yards of such goods, 2,321,338; value of such goods, $382,858: pounds of worsted yarn, not made into cloth, 617,366; value of worsted yarn, $271,708: capital invested, $514,000: males employed, 298; females employed, 548.

Hosiery.—Establishments for the manufacture of hosiery, 17; quantity and description, 134,138; value of hosiery, $62,492: pounds of yarn not made into hosiery, 28,200; value of yarn, $32,400: capital invested, $42,500: males employed, 53; females employed, 185.

Linen.—Establishments for the manufacture of linen, 3; pounds of linen thread, twine, &c., 875,000; value of linen thread, $145,000: capital invested, $79,000: males employed, 93; females employed, 99.

Manufactures of silk.—Silk manufactories, 8; pounds of sewing-silk, 22,509; value of sewing-silk, $150,477: capital invested, $38,000: males employed, 28; females employed, 128.

Rolling, slitting, and nail mills.—Mills, 32; tons of iron not made into nails, 1,236,025: machines for manufacture of nails, 540; pounds of nails, 37,102,400; value of nails, $1,502,275: capital, $1,906,400: hands employed, 1,729.

Forges.—Number of forges, 152; tons of bar-iron, anchors, chain-cables, and other articles of wrought-iron, 5,218; value of bar-iron, chain-cables, and other articles, $538,966: capital invested, $377,685: hands employed, 422.

Pig-iron.—Number of furnaces for manufacture of pig-iron, 4; tons of pig-iron, 4,588; value of pig-iron, $148,761: capital invested, $155,000: hands employed, 235.

Hollow-ware and castings.—Number of furnaces for the manufacture of hollow-ware and castings, other than pig-iron, 91; tons of hollow-ware and castings, other than pig-iron, 20,002; value of hollow-ware and castings, $1,280,141: capital invested, $713,270: hands employed, 1,267.

Machinery.—Establishments for the manufacture of cotton, woolen, and other machinery, 114; gross value of machinery manufactured, $2,022,648: capital invested, $1,103,850: hands employed, 2,421.

Steam engines and boilers.—Establishments for manufacture of, 6; value of steam engines and boilers, $208,546; capital invested, $127,000; hands employed, 221.

Fire engines.—Shops for manufacture of, 6; fire engines, 53; value of fire engines, $37,800; hands employed, 42.

Scythes.—Manufactories, 20; scythes, 170,328; value of scythes, $113,935; capital, $69,590; hands employed, 171.

Axes, hatchets, and other edge tools.—Axe manufactories, 35; axes, hatchets, and other edge tools, 53,537; value of tools, $94,441; capital invested, $48,225; hands employed, 94.

Cutlery.—Establishments for the manufacture of, 14; value of cutlery, $148,175; capital invested, $68,725; hands employed, 197.

Butts or hinges.—Establishments for the manufacture of, 5; number of dozen of iron butts or hinges, 108,280; value of iron butts or hinges, $25,390; capital invested, $3,500; hands employed, 49.

Latches and door handles.—Establishments for manufacture of, 4; number of dozen of latches, &c., 1,300; value of door handles, &c., $3,200; capital invested, $750; hands employed, 10.

Locks.—Manufactories, 11; locks, 46,800; value of, $60,070; capital invested, $23,600; hands employed, 75.

Tacks and brads.—Manufactories, 26; pounds of tacks and brads, 3,058,175; value of tacks and brads, $253,687; capital invested, $123,225; hands employed, 269.

Shovels, spades, forks, and hoes.—Manufactories of, 39; value of shovels, &c., $275,212; capital invested, $123,950; hands employed, 259.

Ploughs.—Manufactories, 73; ploughs and other agricultural tools, 61,334; value of the same, $121,691; capital invested, $58,575; hands employed, 158.

Iron railings, fences, and safes.—Shops for manufacture of, 7; value of, $129,300; capital invested, $53,000; hands employed, 87.

Copper.—Manufactories, 19; pounds of copper, 2,430,000; value of copper, $610,950; capital invested, $329,000; hands employed, 197.

Brass foundries.—Foundries, 26; value of articles manufactured in brass foundries, $331,890; capital invested, $167,600; hands employed, 145.

Britannia ware.—Establishments for the manufacture of, 9; value, $102,550; capital, $49,350; hands employed, 93.

Metal buttons.—Manufactories of, 2; number of gross of, 98,546; value of, $56,080; capital invested, $51,500; hands employed, 60.

Glass.—Manufactories, 10; value of glass ware, $758,300; capital invested, $700,200; hands employed, 630.

Starch.—Manufactories, 6; pounds of starch manufactured from wheat or flour, 2,683,000; value of all the starch, $119,950; capital invested, $37,500; hands employed, 39.

Chemical preparations.—Establishments for manufacture of, 13; value of, $331,965; capital invested, $251,700; hands employed, 113.

Paper.—Manufactories, 89; tons of stock consumed, 12,886; quantity of, tons, 4,765; reams, 607,175; value of paper, $1,750,273; capital invested, $1,144,537; hands employed, 1,369.

Musical instruments.—Manufactories, 31; value of, $548,625; capital invested, $293,100; hands employed, 427.

Clocks.—Manufactories, 9; number of clocks, 21,409; value of clocks, $54,975; capital invested, $10,350; hands employed, 40.

Chronometers, watches, gold and silver ware, and jewelry.—Establishments for manufacture of, 55; value of, $305,623; capital invested, $126,225; hands employed, 293.

Brushes.—Manufactories, 19; value of brushes, $153,900; capital invested, $68,875; hands employed, 220.

Saddles, harnesses, and trunks.—Manufactories of, 299; value of saddles, &c., $422,794; capital invested, $144,540; hands employed, 648.

Upholstery.—Manufactories of, 58; value of, $354,261; capital invested, $124,700; hands employed, 275.

Hats and caps.—Manufactories, 143; number of caps and hats, 677,347; value of hats and caps, $734,942; capital invested, $213,793; hands employed, 1,003.

Cordage.—Manufactories, 49; pounds of cordage, 9,398,783; value of, $906,321; capital invested, $540,930; hands employed, 637.

Cards.—Manufactories, 30; value of cards of all kinds, $323,845; capital invested, $171,500; hands employed, 147.

Salt.—Establishments for manufacture of, 562; bushels of salt, 330,112; value of salt, $79,980; capital invested, $399,285; hands employed, 584.

Railroad cars, coaches, chaises, wagons, sleighs, and other vehicles.—Establishments for manufacture of vehicles, 563; value of vehicles, $1,343,576; capital invested, $553,434; hands employed, 1,881.

Lead.—Manufactories, 11; value of manufactories of lead, $90,880; capital invested, $72,700; hands employed, 50.

Sugar, refined.—Sugar refineries, 2; pounds of sugar, 8,433,000; value of sugar, $940,000; capital invested, $410,000; hands employed, 106.

Oil and sperm candles.—Establishments for manufacture of, 60; gallons of oil, 3,743,828; value of oil, $2,945,493; pounds of spermaceti candles,

2,241,192; value of sperm candles, $668,303; capital invested, $2,451,917; hands employed, 306.

Soap, and tallow candles.—Establishments for manufacture of, 109; barrels of soft soap, 18,949; pounds of hard, 13,350,760; value of all the soap, $666,190; pounds of tallow candles, 1,802,444; value of tallow candles, $169,966; capital invested, $405,872; hands employed, 343.

Powder.—Mills, 11; kegs of, 67,400; value of powder, $165,500; capital invested, $120,000; hands employed, 49.

Fire-arms.—Establishments for manufacture of, 18; number of fire-arms, 24,465; value of fire-arms, $260,819; capital invested, $789,848; hands employed, 357.

Cannon.—Establishments for manufacture of, 3; number of cannon, 277; value of, $82,000; capital invested, $120,000; hands employed, 48.

Chocolate.—Number of mills, 6; pounds of chocolate, 451,901; value of, $81,672; capital invested, $47,500; hands employed, 27.

Chairs and cabinet ware.—Manufactories, 449; value of chairs, &c., $1,476,679; capital invested, $477,374; hands employed, 2,594.

Tin.—Manufactories of tin ware, 231; value of tin ware, $793,624; capital invested, $343,710; hands employed, 719.

Combs.—Manufactories, 71; value of combs, $198,965; capital invested, $73,100; hands employed, 340.

White lead and other paints.—Establishments for manufacture of, 11; pounds of white lead, 2,872,000; value of white lead, $164,000; value of other paints, $192,200; capital invested, $253,500; hands employed, 106.

Linseed oil.—Mills for manufacture of, 4; gallons of oil, 278,000; value of oil, $181,000; capital invested, $77,000; hands employed, 34.

Glue and gums.—Establishments for manufacture of glue and preparation of gums, 20; value of glue and gums, $387,575; capital invested, $283,695; hands employed, 93.

Cotton-gins.—Establishments for manufacture of, 4; value of cotton-gins, $45,444; capital invested, $75,000; hands employed, 48.

Flouring-mills.—Mills, 26; barrels of flour, &c., 63,200; value of flour, $174,805; capital invested, ——— ; hands employed, 30.

Tanneries.—Tanneries, 473; hides tanned, 1,755,858; value of leather tanned and curried, $3,836,657; capital invested, $1,9000,545; hands employed, 2,043.

Boots and shoes.—Number of pairs of boots, 3,768,160; number of pairs of shoes, 17,128,152; value of boots and shoes, $14,799,140; males employed, 27,199; females employed, 18,678.

Straw bonnets and hats, straw braids, and palm-leaf hats.—Number of straw bonnets and hats, 1,046,954; value of straw bonnets and hats, $1,057,892; value of straw braid manufactured, and not made into bonnets or hats, $102,367; number of palm-leaf hats, 2,845,264; value of palm-leaf hats, $489,237; females employed, 13,311.

Bricks.—Number of thousands of bricks, 110,076; value of bricks, $612,832; hands employed, 1,407.

Snuff, tobacco, and cigars.—Value of, $324,639; hands employed, 572.

Mathematical and philosophical instruments.—Value of, $54,050; hands employed, 68.

Building-stone.—Value of building, quarried and prepared, $1,065,599; hands employed, 1,819.

Marble.—Value of marble quarried and prepared, $220,004; hands employed, 312.

Lime.—Casks of, 46,331; value of, $43,629; hands employed, 80.

Mineral coal and iron-ore.—Value of, mined, $21,669; hands employed, 78.

Whips.—Value of, $111,947; hands employed, 35.

Blacking.—Value of, $10,422; hands employed, 35.

Blocks and pumps.—Value of, $127,249; hands employed, 204.

Mechanics' tools.—Value of, $161,899; hands employed, 256.

Wooden ware.—Value of, not otherwise enumerated, including farming utensils, $416,366; hands employed, 806.

Brooms.—Number of corn and other brooms, 1,545,985; value of brooms, $200,814; hands employed, 313.

Steel pens.—Number of gross of steel pens, 30,000; value of, $15,000; capital invested, $5,000; hands employed, 12.

Cooperage.—Value of casks, &c., $269,935; hands employed, 487.

Fringe and tassels.—Manufactories of, 4; value of, $54,300; capital invested, $11,700; hands employed, 106.

Boxes of all kinds.—Value of, $215,105; hands employed, 235.

Earthen ware and stone ware.—Value of, $52,025; capital invested, $15,500; hands employed, 72.

Sashes, doors, blinds, and frames.—Value of, $180,131: hands employed, 215.

Lasts.—Number of, 123,500; value of, $80,145: hands employed, 84.

Lard oil.—Manufactories, 5; gallons of, 274,000; value of, $212,150: pounds of stearine, 112,000; value of stearine, $7,840: capital invested, $91,000: hands employed, 37.

Dyeing.—Amount received for, $98,700: males employed, 79; females employed, 35.

Vessels.—Vessels launched, 112; tonnage, 26,312; value of vessels, $1,172,147: hands employed, 1,017.

Boats.—Boats built, 1,861; value of, $82,943: hands employed, 164.

All other articles manufactured.—Gross value of, $4,758,384: capital invested, $1,587,760: hands employed, 3,232.

Lumber and shingles.—Thousands of lumber, 83,995; value of lumber, $888,245: thousands of shingles, 16,423; value of shingles, $32,861: hands employed, 2,506.

Firewood, bark, and charcoal.—Cords of firewood, 368,554; value of firewood, $1,010,328: cords of bark, 9,957; value of bark, $29,851: bushels of charcoal, 775,925; value of charcoal, $48,477: hands employed, 2,925.

Oil, coal, &c., consumed in manufacturing.—Gallons of sperm oil, 282,754; value of sperm oil, $255,434: gallons of whale oil, 56,548; value of whale oil, $26,043: gallons of all other kinds of oil, 321,369; value of all other kinds of oil, $166,505: tons of anthracite coal, 79,749; value of anthracite coal, $453,411: chaldrons of bituminous coal, mined in the United States, 16,388; value of bituminous coal, mined in the United States, $147,917: chaldrons of foreign bituminous coal, 22,085; value of foreign bituminous coal, $190,405: value of all other articles of American production, excepting cotton, wool, and iron, $3,144,288; value of all other articles of foreign production, excepting cotton, wool, and iron, $2,055,082.

Whale fishery.—Vessels employed in, 479; tonnage, 143,451; gallons of sperm oil, 6,704,716; value of sperm oil, $6,233,276: gallons of whale oil, 9,572,990; value of whale oil, $2,961,619: gallons of other oil, 72,409; value of other oil, $28,754: pounds of whalebone, 2,937,509; value of whalebone, $1,147, 518: capital invested, $11,805,910: hands employed, 11,378.

Mackerel and cod-fishery.—Vessels employed in the mackerel and cod-fisheries, 967; tonnage, 51,796; barrels of mackerel, 86,628; value of mackerel, $637,052: quintals of codfish, 334,901; value of codfish, $746,263: value of other fish and lobsters, $100,822: bushels of salt consumed in the mackerel and cod-fisheries, 491,064: capital invested, $1,238,640: hands employed, 7,866.

Sheep and wool.—Saxony sheep, 33,875; Merino sheep, 165,428; other kinds of sheep, 155,640; value of all the sheep, $558,284: pounds of Saxony wool, 93,218; pounds of Merino wool, 487,050; pounds of all other wool, 435,962; value of all the wool, $365,136.

Asses, horses, cattle, and swine.—Asses and mules, 47; value of, $2,785: horses, 65,181; value of horses, $3,451,118: neat-cattle, 276,549; value of neat-cattle, $5,327,199: swine, 104,740; value of swine, $917,435: value of beef, &c., slaughtered for market, $225,918.

Grain.—Bushels of Indian corn or maize, 1,985,215; value of Indian corn or maize, $1,352,677: bushels of wheat, 47,986; value of wheat, $54,502: bushels of rye, 446,925; value of rye, $328,033: bushels of barley, 121,931; value of barley, $72,261; bushels of oats, 1,238,159; value of oats, $405,657: bushels of buckwheat, 32,274; value of buckwheat, $15,099.

Vegetables, hay, &c.—Bushels of potatoes, 4,767,115; value of potatoes, $1,309,030: bushels of other esculent vegetables, 1,604,789; value of other esculent vegetables, $515,082: tons of millet, 1,339; value of millet, $8,476: tons of hay, 603,482; value of hay, $5,214,357: pounds of flax, 5,896; value, $665.

Fruit.—Bushels of, 2,980,143; value of, $744,540.

Hops.—Pounds of, 365,130; value of, $32,251.

Tobacco.—Pounds of, 265,560; value of, $16,686.

Raw silk.—Pounds of, 194; value of, $952.

Teazles.—Thousands of, 3,148; value of, $3,308.

Butter.—Pounds of, 7,688,556; value of, $1,116,709.

Cheese.—Pounds of, 7,262,637; value of, $398,174.

Honey and Beeswax.—Pounds of honey, 92,055; value of honey, $13,206; pounds of beeswax, 3,118; value of beeswax, $981.

Shoe pegs.—Bushels of, 13,808; value of, $18,206.

Milk.—Gallons of, 2,850,412; value of $304,917.

Maple sugar.—Pounds of, 573,048; value of, $41,443.

Poultry and eggs.—Value of, $25,891.

Garden seeds.—Value of, $4,721.

Berries.—Value of, $10,842.

Broom seed and brush.—Value of $86,111.

N. B.—The secretary of the State says, in his preface, "the returns of agricultural products, in particular, are believed to fall far below the truth."

Summary showing the value of the articles manufactured, the amount of capital invested, and the number of hands employed, according to the returns, in the State of Massachusetts, for the year ending April 1, 1845.

Articles.	Value.	Capital invested.	Hands employed.
Anchors, chain cables, &c.	$538,966	$377,685	422
Axes, hatchets, and other edge tools	94,441	48,225	94
Beef, &c., slaughtered	225,918		
Beeswax	981		
Berries	10,842		
Blacking	10,422	–	35
Bleaching, or coloring	2,166,000	200,500	211
Blocks and pumps	127,249	–	204
Boats	82,943	–	164
Boots and shoes	14,799,140	–	45,877
Boxes of all kinds	215,105	–	235
Brass articles	331,891	167,600	145
Bricks	612,832	–	1,407
Britannia ware	102,550	49,350	93
Broomseed and brush	86,111		
Brooms	200,814	–	313
Brushes	153,900	68,875	220
Butter	1,116,709		
Buttons, metal	56,080	51,500	60
Butts, or hinges	25,390	3,500	49
Calico	4,779,817	1,401,500	2,053
Candles, sperm, and oil	3,613,796	2,451,917	306
Candles, tallow, and soap	836,156	405,872	343
Cannon	82,000	120,000	48
Cards	323,845	171,500	147
Carpeting	834,322	488,000	1,034
Cars, railroad carriages, and other vehicles	1,343,576	553,434	1,881
Chairs and cabinet ware	1,476,679	477,374	2,594
Cheese	398,174		
Chemical preparations	331,965	251,700	113
Chocolate	81,672	47,500	27
Clocks	54,974	10,350	40
Coal, mineral, and iron ore	21,669	–	78
Combs	198,965	73,100	340
Cooperage	269,935	–	487
Copper	610,950	329,000	197
Cordage	906,321	543,930	647
Cotton goods of all kinds	12,193,449	17,739,000	20,710
Cutlery	148,175	68,725	197
Dyeing	98,700	–	114
Earthen and stone ware	52,025	15,500	72
Engines, fire	37,800	–	42
Engines and boilers, steam	208,546	127,000	221
Fire-arms	260,819	789,848	357
Fishery, mackerel and cod	1,484,137	1,238,640	7,866
Fishery, whale	10,371,167	11,805,910	11,378
Flax	665		
Flour and other grain	174,805	44,550	30
Fringe and tassels	54,300	11,700	106
Fruit	744,540		
Gins, cotton	45,444	75,000	48
Glass	758,300	700,000	630
Glue	387,575	283,675	93
Grain	2,228,229		
Hats and Caps	734,942	213,793	1,003
Hay	5,214,357		
Hollow ware and castings, other than pig iron	1,280,141	713,270	1,267

SUMMARY—Continued.

Articles.	Value.	Capital invested.	Hands employed.
Honey	$13,206		
Hops	32,251		
Hosiery and yarn	94,892	$42,500	238
Instruments, mathematical, &c.	54,040	–	68
Iron, pig	148,761	155,000	235
Iron railing, fences, and safes	129,300	53,000	87
Jewelry, including chronometers, watches, gold and silver ware	305,623	126,225	293
Lasts	80,145	–	84
Latches and door handles	3,200	750	10
Lead pipe, and lead manufactures	90,880	72,700	50
Lead, white, and paints	356,200	253,500	106
Leather	3,836,657	1,900,545	2,043
Lime	43,629	–	80
Linen thread	145,000	79,000	192
Linseed oil	181,100	77,000	34
Locks	60,070	23,600	75
Lumber and shingles	921,106	–	2,506
Machinery	2,022,648	1,103,850	2,421
Maple sugar	41,443		
Marble	220,004	–	312
Milk	304,917		
Millet	8,476		
Musical instruments	548,625	293,100	427
Oil, lard	219,990	91,000	37
Oil.—(*See candles and fishery.*)			
Paper	1,750,273	1,144,537	1,369
Pens, steel	15,000	5,000	12
Ploughs and agricultural tools	121,691	58,575	158
Potatoes	1,309,030		
Poultry and eggs	25,891		
Powder	165,500	120,000	49
Rolled and slit iron and nails	2,738,300	1,906,400	1,729
Saddles, harnesses, and trunks	422,794	144,540	648
Salt	79,980	399,285	584
Sashes, blinds, and doors	180,181	–	215
Scythes	113,935	69,590	171
Seeds	4,721		
Shoe pegs	18,206		
Shovels, spades, forks, and hoes	275,212	123,950	259
Silk, raw	952		
Silk, sewing	150,477	38,000	156
Snuff, tobacco, and cigars	324,639	–	572
Soap. (*See candles.*)			
Starch	119,950	37,500	39
Stone, building	1,065,599	–	1,849
Straw bonnets and hats			
Palm-leaf hats and braid	1,649,496	–	13,311
Sugar, refined	940,000	410,000	106
Tacks and brads	253,687	123,225	269
Teazles	3,308		
Tin ware	793,634	343,710	710
Tobacco	16,686		
Tools, mechanics'	161,899	–	256
Upholstery	354,261	124,700	275
Vegetables, other than potatoes	515,082		
Vessels	1,172,147	–	1,017
Whips	111,947	–	526
Wood, (fire) bark and charcoal	1,088,656	–	2,92
Wooden ware	416,366	–	806
Wool	365,136		

SUMMARY—Continued.

Articles.	Value.	Capital invested.	Hands employed.
Woolen goods of all kinds - - - -	$8,877,478	$5,604,002	7,372
Worsted goods - - - - - - -	654,566	514,000	846
Stoves, bread, beer, books and stationery, balances, matches, lamps, pickles, paper hangings, types, umbrellas, &c., &c., &c. - - - -	4,758,384	1,587,760	3,232
Total - - - -	114,478,443	59,145,767	152,766

Number and value of cattle, stock, &c., returned under the act.

Cattle, stock, &c.	Number.	Value.
Asses and mules - - - - - - -	47	$2,785
Cattle - - - - - - - -	276,549	5,327,199
Horses - - - - - - - -	65,181	3,451,118
Sheep - - - - - - - -	354,943	558,284
Swine - - - - - - - -	104,740	917,435
Total - - - - -	801,460	10,256,821

According to the above, the average value of each of these animals is as follows:

Asses and mules about - - - - - -	$59 50
Cattle - - - - - - - -	19 25
Horses - - - - - - - -	52 91
Sheep - - - - - - - -	1 54
Swine - - - - - - - -	8 75

Summary of population, products, manufactures, &c., taken from the State census of New York for the year 1844.

Population, 2,604,495.
No. of acres of improved land, 11,757,276½.

				Aver. No. of bushels per acre.
Barley,	No. of acres, 192,503 4-5	No. of bushels raised,	3,108,704 11-12	about 16 1-10
Peas,	" 117,379	"	1,761,503 1-10	" 15
Beans,	" 16,231 15-19	"	162,187⅔	" 10
Buckwheat,	" 255,495⅔	"	3,634,679 7-12	" 14 1-6
Turnips,	" 15,322 9-23	"	1,350,332	" 88
Potatoes,	" 255,162 3-5	"	23,653,418	" 92⅔
Flax,	" 46,089	No. of lbs. raised,	2,897,062⅛	" 62⅓ lbs.
Wheat, sown,	" 1,013,665	No. of bushels raised,	13,391,770⅔	" 13½
Wheat, harvested,	" 958,233⅞			
Corn,	" 595,135	"	14,722,114⅞	" 24 4-5
Rye,	" 317,099 1-6	"	2,966,322½	" 9⅓
Oats,	" 1,026,915⅛	"	26,323,051	" 26

No. of neat cattle - - - - - - - -	2,072,330
No. of cows milked - - - - - - - -	999,490
No. of pounds of butter made - - - - - - -	79,501,733½
No. of pounds of cheese made - - - - - - -	36,744,976
No. of horses - - - - - - - - -	505,155
No. of sheep - - - - - - - - -	6,443,855
No. of fleeces - - - - - - - - -	4,607,002½
No. of pounds of wool - - - - - - - -	13,864,828
No. of hogs - - - - - - - - -	1,584,344

	Value of raw material.	Value of manufactured articles.
No. of grist mills, 1,984 - - -	$18,580,372 20	$22,794,474 29
No. of saw mills, 7,406 - - -	4,210,713 38	7,577,154 28
No. of oil mills, 87 - - - -	1,363,074 50	1,695,025 50
No. of fulling mills, 740 - - -	1,125,539 78	1,660,881 25
No. of carding mills, 820 - - -	1,416,904 07	1,678,320 42

No. of cotton factories, 118; value of raw material, $1,132,702 12; value of manufactured article, $2,877,500 29; No. of yards of cloth manufactured, 31,234,633¾.

No. of woolen factories, 345; value of raw material, $2,877,804 55; value of manufactured article, $4,281,257 31; No. of yards of cloth manufactured, 4,916,998 7-12; No. of yards of woolen and cotton, 1,592,899½.

	Value of raw material.	Value of manufactured articles.
No. of iron works, 500 - - -	$4,451,674 84	$8,402,586 63
No. of trip hammers, 156 - - -	284,360 00	586,328 00
No. of distilleries, 221 - - -	3,162,586 56	4,222,154 59
No. of asheries, 738 - - -	613,516 44	909,194 85
No. of glass factories, 15 - - -	115,200 00	378,700 00
No. of rope factories, 79 - - -	659,413 00	918,540 00
No. of chain-cable factories, 7 - -	2,500 00	5,000 00
No. of oilcloth factories, 24 - -	167,992 00	270,260 00
No. of dyeing and printing factories, 18 -	1,497,038 25	2,086,986 35
No. of clover mills, 115 - - -	107,803 72	124,567 00
No. of paper mills, 82 - - -	369,966 50	702,505 44
No. of tanneries, 1,414 - - -	4,052,949 95	6,585,006 31
No. of breweries, 102 - - -	805,597 50	1,313,273 00

No. of silk incorporated manufactories, 71; unincorporated, 1,608.
No. of merchants, 20,758.
No. of manufacturers, 13,088.
No. of mechanics, 3,549.

INDEX.

K.—*Classified list of patents granted during the year 1845, with the names of patentees, places of residence, and date of patent.*

CLASS I.—AGRICULTURE, INCLUDING INSTRUMENTS AND OPERATIONS.

75

Inventions or discoveries.	Patentees.	Residence.	When issued.
Bee-hives	Elias Jones	Amsterdam, N. Y.	February 12, 1845
Bee-hives	Silas Hart	New Haven, N. Y.	March 26, 1845
Bee-hives	Abraham Sanburn	Carthage, Ohio	March 26, 1845
Bee-hives	Clark Wheeler	Little Valley, N. Y.	June 20, 1845
Bee-hives	Israel Lamborn	Marshallton, Pa.	August 26, 1845
Bee-hives	Christopher Suydam	Lambertsville, N. J.	November 18, 1845
Bee-hives	James Robb	Lewiston, Pa.	December 31, 1845
Bee-hives	Aaron Colton	Pittsfield, Vt.	December 31, 1845
Bee-hives, entrance to	George Upham	Hebron, Ohio	May 1, 1845
Bee-house	Abraham Decker	Walnut township, Ohio	July 30, 1845
Bees, managing	Elias Parks	Wheatfield, N. Y.	July 22, 1845
Clover mill, for hulling, &c., (patent dated May 4	Henry Hizer	Wooster, Ohio	June 14, 1845
Clover mill, for hulling, &c.	Samuel W. Powell	Turbet, Pa.	August 16, 1845
Corn-fodder, cutting and crushing	Hiram A. Pitts	Winthrop, Maine	May 1, 1845
Corn-sheller	Joseph D. Briggs	Saratoga, N. Y.	June 14, 1845
Corn-sheller	Thomas D. Burrall	Geneva, N. Y.	December 6, 1845
Cotton-cleaner	Fones McCarthy	Demopolis, Ala.	February 12, 1845
Cultivator	Almond Harrison	Blissfield, Mich.	September 2, 1845
Cultivator	Andrew Ralston	West Middleton, Pa.	September 2, 1845
Cultivator	Allen Eldred	Openheim, N. Y.	December 20, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Cultivator and seed-planter	R. H. Springsteed	Wooster, Ohio	February 12, 1845
Cultivator tooth	David B. Rogers	Stafford, N. Y.	November 1, 1845
Cutting and grinding fodder	Jacob Royer	Uniontown, Md.	March 12, 1845
Flax-pullers	James H. Bennett	East Bennington, Vt.	January 23, 1845
Harvesting machine	Erastus C. West	Bradford, Vt.	June 25, 1845
Mowing, reaping machine	Cyrus H. McCormick	Rockbridge, Va.	January 31, 1845
Mowing, reaping machine	Ferdinand Woodward	Upper Freehold, N. J.	September 30, 1845
Planting machine	Enoch Woods	Beloit, Wisconsin Ter'y	January 10, 1845
Plough	Bancroft Woodcock	Wheeling, Va.	January 31, 1845
Plough	Seth J. Roberts	Jeffersonville, Pa.	February 12, 1845
Plough	Ephraim Ball	Greentown, Ohio	February 20, 1845
Plough	Samuel Shearer	Big Prairie, Ohio	July 14, 1845
Plough	William Bullock	Jersey City, N. J.	July 30, 1845
Plough	John Ball	Greentown, Ohio	November 8, 1845
Plough, hill-side	Joseph Trump	Connelsville, Pa.	September 9, 1845
Plough, clevis	Patrick Gallager	Chambersburg, Pa.	Nov. 26, 1845; antedated May 26, 1845.
Plough, wheel	T. B. Quigley and H. Hall	Mansfield, Ohio	October 7, 1845
Sowing machine	Pierpont Seymour	East Bloomfield, N. Y.	May 7, 1845
Smut machine	Joseph Johnson	Wilmington, Del.	Nov. 8, 1845; antedated Septemb'r 9, 1845.
Straw-cutter	Daniel M. Sechler	Wooster, Ohio	February 20, 1845
Straw-cutter	Grey Utley	Chapel Hill, N. C.	September 27, 1845

Threshing machine	J. T. & E. Warren	New York	July 14, 1845
Winnowing machine	Isaac T. Grant	Schaghticoke, N. Y.	July 10, 1845
Winnowing machine	Anthony Cooley	Kalamazoo, Mich.	September 2, 1845

CLASS II.—METALLURGY, AND MANUFACTURES OF METALS AND INSTRUMENTS THEREFOR.

Dies for cutting and forming cultivator teeth	David B. Rogers	Stafford, N. Y.	November 8, 1845
Door-fastenings	Jno. C. Palmer	East Haddam, Conn.	October 7, 1845
Files, machine for cutting	Solomon Whipple	Albany, N. Y.	February 12, 1845
Forge, hot-blast	Paul A. Sabbaton	Reading, Pa.	February 24, 1845
Forks, manufacture of	Samuel H. Gilman	Boston, Mass.	October 16, 1845
Forge, portable	Christian V. Queen	Peekskill, N. Y.	November 18, 1845
Hammer, working forge	George Escol Sellers	Cincinnati, Ohio	January 10, 1845
Hammers	Solomon Anderson	Garretsville, N. Y.	August 20, 1845
Hinges for fastening blinds and shutters	Robert B. Varden	Baltimore, Md.	February 12, 1845
Hoe-necks	Nathan Brand	Leonardsville, N. Y.	April 1, 1845
Knobs for doors	George O. Russell	Middletown, Ct.	October 7, 1845
Latches for doors	Jacob Alrich	Wimington, Del.	May 24, 1845
Lock, door	George Oates	Charleston, S. C.	September 2, 1845
Lock for banks and safes, &c.	John Oxnard	Portland, Me.	April 10, 1845
Lock for banks and safes, &c.	William Hall	Boston, Mass.	October 16, 1845
Locks and keys	Angus McKennon	New York	August 16, 1845
Lock and latch combined	Rhodolphus Kingsley	Springfield, Mass.	April 16, 1845
Lock for safes, &c.	Henry Isham	Montpelier, Vt.	November 12, 1845
Lock for vaults, &c.	Henry C. Jones	Newark, N. J.	April 26, 1845
Metallic cores for pipe boxes	John Huntington	Zanesville, Ohio	February 24, 1845
Ores, iron, method of reducing, &c.	Wm. Neal Clay Assig'd to Wm. Green, jr.	England Woodbridge, N. J.	July 5, 1845
Pipe, lead, machine for making	Nathan Buttrick, jr.	Chelmsford, Mass.	November 8, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Pipes, machine for riveting	Jonathan Ball	New York	December 20, 1845
Pins, machine for heading and pointing	Samuel G. Reynolds	Bristol, R. I.	December 31, 1845
Rivets, machine for making	Horatio G. Reed	Scituate, Mass.	March 12, 1845
Saw filing	Jacob Arndt	Wheeling, Va.	February 24, 1845
Screws, manufacture of	Simeon Brooks and Wm. N. Clark	Chester, Ct.	January 23, 1845
Screws, machine for finishing	Cullen Whipple	Providence, R. I.	July 10, 1845
Sheet-iron, machine for bending	Henry A. Roe	Erie, Pa.	September 11, 1845
Spike machine, (improvement on Burden's patent)	John F. Winslow and Israel Blanchard	Troy, N. Y.	May 10, 1845
Tin-ware, machine for double seaming	Daniel Newton	Louisville, Ky.	December 20, 1845; antedated July 7, 1845.
Tools, machine for grinding	William Hovey	Worcester, Mass.	September 23, 1845
Vice	William H. Taylor and A. P. Norton	Rochester, N. Y. Waterville, N. Y.	May 16, 1845
Wire, machine for beating and cleaning	John J. Howe	Derby, Ct.	December 26, 1845

CLASS III.—MANUFACTURES OF FIBROUS AND TEXTILE SUBSTANCES, INCLUDING MACHINES FOR PREPARING FIBRES OF WOOL, COTTON, SILK, FUR, PAPER, ETC.

Brushes for cotton gins	Edwin Keith	Bridgewater, Mass.	September 9, 1845
Burring machine	Thomas S. Washburn	Lowell, Mass.	October 11, 1845

Burring machine	Alanson Crane	Lowell, Mass.	October 11, 1845
Cloth, felting apparatus	John Andrews	Bellville, N. J.	January 31, 1845
Cotton roving, laying in cans	John Tatham and David Cheetham	Rockdale, England	March 14, 1844, in England; Nov'r 18, 1845, U. S. A.
Cotton wadding, machine for	Oliver Tenny	Dorchester, Mass.	January 10, 1845
Cotton whippers and cleaners	Jane A. Davis, adm'x of Henry G. Davis, dec'd	Clark county, Ala.	May 16, 1845
Carding machine	Hugh Whiteman	Pittsburg, Pa.	February 12, 1845
Gin, cotton saw	Eleazer Carver	Bridgewater, Mass.	January 4, 1845
Gin, cotton and wool	Stephen R. Parkhurst	New York	May 1, 1845
Gin, cotton roller	Theodore Ely	New York	December 11, 1845
Hat-bodies, fabrics for	Isaac L. Chapman	New York	May 1, 1845
Hat-bodies, mode of forming	Marmaduke Osborne	New York	November 11, 1845
Hats, equalizing and polishing nap of	John Lowdon and Thos. Shaw	New York	May 7, 1845
Hats, manufacture of	John N. Genin	New York	July 22, 1845
Hemp-brake	Coleman C. Estes	Maury county, Tenn.	July 14, 1845
Hemp, breaking and cleaning	George W. Billings and John Harrison	Glasgow, Mo.	June 7, 1845
Hemp-dressing machine	George W. Billings and John Harrison	Glasgow, Mo.	May 1, 1845
Hemp, &c., machine	Richard Deering, sen.	Louisville, Ky.	June 10, 1845
Hemp breaker	P. G. Gardiner	New York	February 28, 1845
Hemp and flax breaking and dressing	Benjamin M. Smith	Massillon, Ohio	October 7, 1845
Hemp and flax dressing	William Y. Singleton	Springfield, Ill.	May 7, 1845
Loom, power	James Nield	Taunton, Mass.	March 15, 1845
Loom, power	James Nield	Taunton, Mass.	March 15, 1845
Loom, power	Daniel Barnum	Bridgeport, Ct.	March 26, 1545
Loom, hand, for weaving fabrics	William Townshend	Rochester, N. H.	April 10, 1845
Loom, power, for weaving plaid	Erastus B. Bigelow	Boston, Mass.	April 10, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Looms, operating shuttles of	R. P. Cunningham	Abington, Ct.	December 16, 1845
Looms, stop apparatus for	Enoch Burt	Manchester, Ct.	June 20, 1845
Loom temples	Erastus B. Bigelow	Boston, Mass.	February 24, 1845
Loom warps, regulating tension	Erastus B. Bigelow	Boston, Mass.	March 12, 1845
Loom weaving	Phœnix Manufacturing Company, assignees of Benjamin Slingerland	Paterson, N. J.	April 1, 1845
Paper, manufacturing	Arthur Varnham	London, England	August 9, 1845
Paper, machine for separating sand, &c., from pulp, in the manufacture of	William Bishop	Coventry, Conn.	December 31, 1845
Printing, calico	Alexander Boyd	Providence, R. I.	April 22, 1845
Ropes, making	Charles Durfee, assignee of Edw'd S. Townsend	Palmyra, N. Y.	February 28, 1845
Speeder-fliers	Erastus B. Bigelow	Boston, Mass.	February 24, 1845
Spindle, mode of steadying the live	Alexander Anderson	Paterson, N. J.	November 21, 1845
Spinning, driving bobbins	William Baxter	Paterson, N. J.	September 30, 1845
Throstle for spinning	Benjamin Brundred	Paterson, N. J.	September 9, 1845
Wool, burring and cleaning	Theodore Ely	New York	May 16, 1845

CLASS IV.—CHEMICAL PROCESSES, MANUFACTURES, AND COMPOUNDS, INCLUDING MEDICINES, DYING, COLOR-MAKING, DISTILLING, SOAP AND CANDLE MAKING, MORTARS, CEMENTS, ETC.

Bagasse, drying	George Merrick	New Orleans, La.	April 10, 1845
Bleaching apparatus	Moses Pierce	Norwich, Conn.	November 8, 1845
Blow-pipes, hydro-oxygen	Robert Hare, M. D.	Philadelphia, Pa.	July 5, 1845
Cements, mastic	William H. Chase	Pensacola, Fa.	April 16, 1845
Cements, water-proof	William Y. Singleton	Springfield, Ill.	December 26, 1845
Composition for bearings of machinery	J. S. Hill and Joseph Dixon	Boston, Taunton, Mass.	January 31, 1845
Composition for removing acid, grease, &c., from cloth	Solomon Guess	Boston, Mass.	August 26, 1845
Die-stuffs from spent madder	Frederick Pfanner	Providence, R. I.	September 13, 1845
Gaslight	Benj. F. Coston	Washington, D. C.	January 31, 1845
Gelatine, preparation of portable	Peter Cooper	New York	June 10, 1845
Hemp preparation	Richard Deering, sen.	Louisville, Ky.	June 25, 1845
Hemp preparation	Thomas H. Barlow	Lexington, Ky.	June 25, 1845
Hemp rotting	George W. Billings and John Harrison	Glasgow, Mo.	May 10, 1845
Hose, combination	Horace H. Day	Jersey City, N. J.	August 16, 1845
India rubber, manufacture of	Nelson Goodyear	Newtown, Conn.	April 22, 1845
India rubber fabrics	Nelson Goodyear	Newtown, Conn.	May 13, 1845
India rubber fabrics	Charles Cooper	New York	June 10, 1845
India rubber threads, machine for cutting	Horace H. Day, H. G. Tyre and J. Helm	Jersey City, New Brunswick, N. J.	June 7, 1845
India rubber threads, machine for cutting	James Bogardus	New York	November 21, 1845; antedated May 21, 1845.

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
India rubber, shirring machine	James Bogardus	New York	November 21, 1845; antedated May 21, 1845.
Ink, printers'	Edward Clark	Brooklyn, N. Y.	July 5, 1845
Lead pipes, method of tinning	R. W. Lowber, assignee of Ward, Selden, and Kneeland	New York	March 12, 1845
Liquids, skimming	Charles Harrival	Baton Rouge, La.	April 26, 1845
Oil from rosin	William T. Clough	Jersey City, N. J.	April 22, 1845
Paints, water-proof	Thomas E. Warren	Troy, N. Y.	March 15, 1845
Plasters, adhesive	William H. Shecut and Horace H. Day	New York	March 26, 1845
Provisions, curing meats	George A. Scherpf	New York	May 7, 1845
Provisions, preparing	D. Lardner & J. Davidson	New York	August 9, 1845
Potatoes, mode of preserving	Charles S. Edwards	Rushville, Ind.	December 31, 1845
Potash, chromate of	Isaac Tyson, jr.	Baltimore, Md.	October 9, 1845
Salt making	James S. O. Brooks	Kanawha, Va.	February 12, 1845
Salt water, separating impurities	Nehemiah P. Stanton	Syracuse, N. Y.	August 20, 1845
Sugar-making	J. De Bretton, sen.	New Orleans, La.	May 24, 1845
Sugar-making	Ethan Campbell	New York	October 25, 1845
Sugar-making	Joseph Francis Lapice, assignee of Charles Louis Derosne	France	Date of foreign patent unknown; July 10, 1845.
Sugar-boilers	Francis Duplessis	Plaquemines, Louisiana	December 16, 1845

CLASS V.—CALORIFIC; COMPRISING LAMPS, FIRE-PLACES, STOVES, GRATES, FURNACES FOR HEATING BUILDINGS, COOKING APPARATUS, PREPARATION OF FUEL, ETC.

Bakers	John T. Davy	Troy, New York	February 12, 1845; antedated August 12, 1844.
Bakers	William Tainter & H. S. Orton	Porter county, Indiana	August 9, 1845
Chimneys, cure for smoky	Augustus Haman	Washington, D. C.	July 22, 1845
Chimneys, cure for smoky	John Plant	Washington, D. C.	November 20, 1845
Furnaces, hot air	Gardner Chilson	Boston, Massachusetts	August 4, 1845; antedated February 4, 1845.
Furnaces, hot air	Adrian Janes	New York	August 9, 1845
Furnaces, air heating	Ebenezer Barrow	New York	December 11, 1845
Furnaces, portable hot air	H. L. B. Lewis	New York	September 19, 1845
Gas burner	William Black	Boston, Massachusetts	August 9, 1845
Grate, parlour	James Wilson	New York	September 13, 1845
Gridirons	Joseph Hawkins	West Windsor, New York	March 26, 1845
Hatters' kettles	Russell Wildman	Hartford, Connecticut	November 8, 1845
Hot water, circulation of	William Beebe	New York	December 16, 1845
Lamps	P. F. Slane & John Golding	East Cambridge, Mass.	January 23, 1845; antedated July 23, 1844.
Lamps for burning lard oil	Andrew Keyser	Fulton, Missouri	August 20, 1845
Lamps regulating draught	E. Whelan	Philadelphia, Pa.	March 26, 1845
Lamp, wicks	Samuel Rust	New York	May 10, 1845; antedated April 4, 1845.

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Lamp wicks, tubes for	James Maclean	Philadelphia, Pa.	December 26, 1845.
Oil feeders	Eliphalet S. Scripture	Syracuse, New York	March 15, 1845.
Ranges, cooking	Moses Pond	Boston, Massachusetts	May 29, 1845.
Ranges, cooking	Jordan L. Mott	New York	November, 1, 1845.
Stoves	John Morrison	Newark, New Jersey	March 12, 1845.
Stoves	Samuel Utter	New York	May 1, 1845.
Stoves	Francis L. Heddenburg	New York	May 7, 1845.
Stoves	Jehiel T. Farrand	Port Byron, New York	August 4, 1845.
Stoves	Peter J. Clute	Schenectady, New York	September 19, 1845.
Stoves, air tight	Anson Atwood	Troy, New York	March 26, 1845.
Stoves, ash pit of	William Butcher	Philadelphia, Pa.	November 29, 1845.
Stoves, coal	Henry Stanley	West Poultney, Vt.	January 4, 1845.
Stoves, coal	Charles Babcock	East Haddam, Ct.	June 10, 1845.
Stoves, coal	Jordon L. Mott	New York	November 1, 1845.
Stoves, cooking	Charles Wolf	Cincinnati, Ohio	January 10, 1845.
Stoves, cooking	Robert Wilson	Williamsport, Pa.	February 20, 1845.
Stoves, cooking	John T. Davy	Troy, New York	March 12, 1845.
Stoves, cooking	Gould Thorp	New York	March 26, 1845.
Stoves, cooking	Henry N. Gros	Palatine Bridge, N. Y.	May 13, 1845.
Stoves, cooking	Theophilus Smith	Galway, New York	June 10, 1845.
Stoves, cooking	E. Johnson & D. B. Cox	Troy, New York	July 22, 1845.
Stoves, cooking	Hosea Huntley	Rochester, New York	August 9, 1845.
Stoves, cooking	Low & Leake	Albany, New York	August 20, 1845.
Stoves, cooking	B. T. Roney	Attleborough, Pa.	September 11, 1845.
Stoves, cooking	Charles J. Woolson	Cleveland, Ohio	September 9, 1845.

Stoves, cooking	P. Low, J. B. Choltar, and E. Jones	Troy, New York	November 8, 1845.
Stoves, cooking	R. Peck & J. W. Cochrane	Attica, New York	November 12, 1845.
Stoves, cooking	John Potter	Gettysburg, Pennsylvania	November 18, 1845.
Stoves, cooking	Eli C. Robinson	Troy, New York	November 26, 1845; antedated August 30, 1845.
Stoves, cooking	Samuel Pierce	Peekskill, New York	December 6, 1845,
Stoves, cooking	Samuel Myres	Schenectady, New York	December 31, 1845; antedated August 9, 1845.
Stoves for fire places	H. Katussowski & F. P. Wiezbicki	New York	December 11, 1845.
Stoves, parlour	James Pedder	Philadelphia, Pa.	September 30, 1845.
Stoves, rotary top	Henry Stanley	West Poultney, Vermont	October 25, 1845.
Stoves, portable	C. L. H. Webb	Lockport, New York	December 6, 1845; antedated August 30, 1845.

CLASS VI.—STEAM AND GAS ENGINES, INCLUDING BOILERS AND FURNACE THEREFOR, AND PARTS THEREOF.

Boiler, steam	James Montgomery	Memphis, Tennessee	December 26, 1845.
Boiler, steam, prevent explosions	Cadwallader Evans	Pittsburg, Pennsylvania	February 24, 1845.
Boiler, steam, prevent explosions	William M. Wright	Pittsburg, Pennsylvania	February 24, 1845.
Boiler, steam, magnetic water-gauge	George Faber	Canton, Ohio	November 26, 1845.
Boiler, steam, removing incrustation	Louis Antoine Ritterbandt	Poland	September 11, 1845; date of foreign patent December 2, 1844.

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Boiler, steam, safety apparatus	James Montgomery	Memphis, Tennessee	September 2, 1845.
Boiler, steam, safety-valve	Abram Patterson	Rush, Pennsylvania	March 21, 1845.
Locomotive wheels, mode of removing, &c.	Thomas D. Simpson	Norwich, Connecticut	September 30, 1845.
Spark-arrester	Samuel Sweet, jr.	New York	May 13, 1845.
Spark-arrester	William C. Grimes	Philadelphia, Pa.	June 7, 1845; antedated March 1, 1845.
Spark-arrester	William C. Grimes	Baltimore, Maryland	May 13, 1845; antedated January 1, 1845.
Spark-arrester	William C. Grimes	Baltimore, Maryland	September 23, 1845.
Spark-arrester	William Duff	Baltimore, Maryland	September 30, 1845.
Steam engine	R. F. Loper	Philadelphia, Pa.	November 26, 1845.
Steam engine	John Ericsson	New York	December 20, 1845.
Steam engine, auxiliary	John Cochrane	Baltimore, Maryland	April 16, 1845.
Steam engine, connecting cylinder and chest	Frederick E. Sickels	New York	September 19, 1845.
Steam engine, connecting cranks of	Frederick E. Sickels	New York	September 19, 1845.
Steam engine cut-off valves	Frederick E. Sickels	New York	September 19, 1845.
Steam engine cut-off valves	John Cochrane	Baltimore, Maryland	April 16, 1845.
Steam engine cut-off valves	Thomas Rogers	Paterson, New Jersey	May 1, 1845.
Steam engine, reacting rotary	James Black	Williamsport, Pa.	March 12, 1845.
Steam engine, rotary	William Wright	Rochester, New York	September 9, 1845.
Steam engine, vibrating	J. H. Towne	Philadelphia, Pa.	January 10, 1845.
Steam valves	Samuel Tabbott	Richmond, Virginia	February 28, 1845.

CLASS VII.—NAVIGATION AND MARITIME IMPLEMENTS, COMPRISING ALL VESSELS FOR CONVEYANCE ON WATER, THEIR CONSTRUCTION, RIGGING, AND PROPULSION, DIVING DRESSES, LIFE-PRESERVERS, ETC.

Boats and other vessels of sheet iron	Joseph Francis	New York	March 26, 1845.
Booms, saddle and jaws for	James Davis, jr.	Gloucester, Massachusetts	December 26, 1845.
Propeller	Horatio Hubbell	Moyamensing, Pa.	July 14, 1845.
Propeller	Leonard Phleger	Wilmington, Delaware	September 13, 1845.
Propeller, submerged	Samuel B. Howd	Arcadia, New York	June 14, 1845.
Propeller, screw	John Ericsson	New York	September 9, 1845.
Propellers, shipping and unshipping	Stephen R. Parkhurst	New York	November 26, 1845.
Propellers, mode of elevating and depressing	R. F. Loper	Philadelphia, Pa.	November 26, 1845.
Propelling boats and other vessels	Gerret Erkson	Pittsburg, Pennsylvania	March 26, 1845.
Propelling canal boats, &c.	Josephus Echols	Columbus, Georgia	November 26, 1845.
Ships' anchors	N. P. Jones & Jas. Raisbeck	New York	July 5, 1845.
Ships' cables, relieving, &c.	Levi Bissell	Brooklyn, New York	February 28, 1845.
Ships' moorings, &c.	Alexander Mitchell	Belfast, Ireland	April 1, 1845; date of foreign patent July 4, 1843.
Ships, sails for	James Maull	Philadelphia, Pa.	December 11, 1845.
Vessels, attaching keels, &c.	Thomas F. Griffith	New Market, Maryland	April 26, 1845.
Vessels' yards, trusses for	John W. Wilson	Philadelphia, Pa.	December 20, 1845.

CLASS VIII.—MATHEMATICAL, PHILOSOPHICAL, AND OPTICAL INSTRUMENTS, INCLUDING CLOCKS, CHRONOMETERS, ETC.

Clocks	Eli Terry	Plymouth, Connecticut	August 9, 1845.
Clocks, propelling power	Joseph Ives	Bristol, Connecticut	February 24, 1845.

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Electro-magnetic telegraph, mode of operating	Ezra Cornell	Ithaca, N. Y.	December 20, 1845
Globes, mounting	Silas Cornell	Rochester, N. Y.	July 5, 1845
Telescope, sub-marine	Sarah P. Mather	Brooklyn, N. Y.	April 16, 1845
Time-keeper, balance for	J. Bliss and F. Creighton	New York	August 4, 1845

CLASS IX.—CIVIL ENGINEERING AND ARCHITECTURE, COMPRISING WORKS ON RAIL AND COMMON ROADS, BRIDGES, CANALS, WHARVES, DOCKS, RIVERS, DAMS, AND OTHER INTERNAL IMPROVEMENTS, BUILDINGS, ROOFS, ETC.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Bridges	Nathan Rider	Worcester, Mass.	November 26, 1845
Bridges, wooden	George W. Thayer	Springfield, Mass.	April 26, 1845
Canal and railroad combined	Samuel S. Walley	Charlestown, Pa.	December 11, 1845
Doors, weather-strips for	A. S. Pelton	Clinton, Conn.	December 16, 1845
Doors and windows, mode of hanging	Aaron B. Carpenter	New York	September 11, 1845
Excavator	Oliver Allen	Norwich, Conn.	May 1, 1845
Excavator, deepening rivers, &c.	Henry McCarty	Pittsburg, Pa.	April 1, 1845
Excavator, ditching machine	Robert Cummings	Lima, Ind.	July 14, 1845
Excavator, ditching and road	Daniel S. Stafford	Rochester, Ill.	June 10, 1845
Gates, balance and sliding	Amon Baker	Western, N. Y.	April 10, 1845
Gates and gateways	Andrew Hood	New York	December 16, 1845
Hydraulic structures	Isaiah W. P. Lewis	Boston, Mass.	May 1, 1845
Raising wrecks of vessels, &c.	Phineas Bennet	New York	September 2, 1845

Rocks, machine for drilling	Hiram H. Scoville	Chicago, Ill.	September 9, 1845
Rock and earth boring apparatus	T. S. Speakman and R. A. Stratton	Philadelphia, Pa.	September 17, 1845
Window sash	C. J. Shirrer and T. W. Cross	Boston, Mass.	March 21, 1845

CLASS X.—LAND CONVEYANCE, COMPRISING CARRIAGES, CARS, AND OTHER VEHICLES USED ON ROADS, AND PARTS THEREOF.

Boxes, anti-friction, for car axles	Thos. Murray Megget, assignee of William Rowan	New Orleans, La. Belfast, Ireland	Oct. 9, 1845; date of foreign patent, Nov. 7, 1844.
Brakes for carriage wheels	William Dunning	Dunningsville, Pa.	November 1, 1845
Brakes for carriage wheels	David D. Gibson and Walter Cobb	Damascoville, Ohio	February 12, 1845
Car bodies, mode of hanging	Levi B. Thyng	Lowell, Mass.	November 18, 1845; antedated May 18, 1845.
Car, railroad, connecting links for	Richard Hemming	Boston, Mass.	October 11, 1845
Car, railroad, replacing upon track	Samuel H. Bean	Philadelphia, Pa.	October 11, 1845
Carriages	John T. Kimball	Kennebunk, Maine	July 22, 1845
Carriage bodies, hanging	Arnold Hosmer	Bath, Ohio	June 2, 1845
Carriage, locomotive, connecting three or more sets of driving wheels	Holmes Hinckley	Boston, Mass.	April 1, 1845
Coaches, steam	James Semple	Alton, Illinois	May 1, 1845
Cart bodies, mode of operating	Thomas Mussey	New London, Conn.	November 1, 1845
Inclined planes, mode of ascending and descending by locomotives, &c.	Ezra Coleman	Philadelphia, Pa.	December 31, 1845
Rails for railroad trucks	W. M. C. Cushman	Albany, N. Y.	January 16, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Railroads	John Elgar	Brookfield, Md.	March 12, 1845
Railway, atmospheric	James Pilbrow	England	July 26, 1845; date of foreign patent, May 17, 1844.
Trucks for railroads	Fowler M. Ray	New York	March 21, 1845
Wheels for carriages	Gershom L. Ackerman	Troy, N. Y.	April 16, 1845; antedated Oct. 16, 1844.
Wheels for carriages, construction of	Eliphalet S Scripture	Syracuse, N. Y.	April 1, 1845
Wheels, railroad car	George W. Eddy	Waterford, N. Y.	December 26, 1845
Wheel-hub, pipe box for	James Jones	Galway, N. Y.	April 1, 1845

CLASS XI.—HYDRAULICS AND PNEUMATICS, INCLUDING WATER WHEELS, WINDMILLS, AND OTHER IMPLEMENTS OPERATED ON BY AIR OR WATER, OR EMPLOYED IN THE RAISING AND DELIVERY OF FLUIDS.

Bellows, double	William Lillie	Edwards, N. Y.	June 2, 1845
Engine, fire	Earnest Morse	New York	December 20, 1845
Filters and refrigerators	Joseph T. Craddock	Baltimore, Md.	December 31, 1845
Pumps	Joseph H. Webster	St. Louis, Mo.	February 28, 1845
Pumps	Frederick Walther	Winchester, Va.	May 1, 1845
Ram, hydraulic	Benjamin S. Benton	Harford, Md.	December 26, 1845
Ram, water	Erastus W. Ellsworth	East Windsor, Ct.	December 6, 1845
Water-wheel	James Gardner	South Lee, Mass.	January 16, 1845

Water-wheel	Chadiah Aylesworth	Bainbridge, N. Y.	March 21, 1845
Water-wheel	John J. Springsteen	Oswego, N. Y.	May 16, 1845
Water-wheel	James Leffel	Springfield, Ohio	May 21, 1845
Water-wheel	Theodore R. Timby	Cato 4 Corners, N. Y.	June 7, 1845
Water-wheel	R. C. Grant	Pomeroy, Ohio	July 26, 1845
Water-wheel	William Dripps	Coatesville, Pa.	November 26, 1845; antedated May 26, 1845.
Water-wheel	John Mecay	Millsborough, Pa.	December 26, 1845
Water-wheel, re-action	Orin W. Seely, (assignee of Joshua Evered	Sodus, N. Y.	July 30, 1845
Water-wheel, re-action	Abner Chapman	Fort Miller Bridge, N. Y.	July 30, 1845

CLASS XII.—LEVER, SCREW, AND OTHER MECHANICAL POWER, AS APPLIED TO PRESSING, WEIGHING, RAISING, AND MOVING WEIGHTS.

Press, cotton	William Bulloch	Jersey City, N. J.	January 4, 1845
Press, cotton	Philos B. Tyler	Philadelphia, Pa.	January 16, 1845
Press, cotton	Joseph Slocum	Syracuse, N. Y.	April 22, 1845
Press, cotton and other	P. G. Gardiner	New York	February 28, 1845
Press, cotton and other	Daniel Gross, assignee of Joseph C. Colt	New York	April 22, 1845
Press, self acting cheese	C. Stone and G. S. Collins	Rootstown & Ravenna, O.	May 29, 1845
Raising and lowering weights	Ephraim Morris	New York	July 5, 1845
Toggle joint, mode of adjusting	S. W. Bulloch	Williamsburg, N. Y.	July 10, 1845

K—LIST OF PATENTS GRANTED DURING THE YEAR 1845.—Continued.

CLASS XIII.—GRINDING-MILLS AND MILL GEARING, CONTAINING GRAIN MILLS, MECHANICAL MOVEMENTS, HORSE-POWER, ETC.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Bark-mill	Anson P. Norton & Morris Owen	Sangerfield, N. Y.	June 25, 1845
Bark-mill	Amos Linsey	Canton, Me.	December 26, 1845
Bark-mill	Milo J. Whiton, assignee of Isaiah Scudder	Broadalbin, N. Y. Plattsville, N. Y.	October 25, 1845; antedated April 25, 1845.
Bolt, flour	Robert Mauck	Honeyville, Va.	December 26, 1845
Coffee-mill	Jesse Fitzgerald	New York	June 25, 1845
Coffee-mill	Beriah Swift	Washington, N. Y.	August 16, 1845
Grinding, corn and cob-mill for	E. A. Knowlton	Columbia, S. C.	February 12, 1845
Grinding, corn and cob-mill for	Jesse Urney	Wilmington, Del.	October 25, 1845
Grinding, corn and cob-mill for	James P. Ross	Lewisburg, Pa.	November 1, 1845
Grinding-mills, &c.	Josiah Platt	Bridgeport, Ct.	December 26, 1845
Grindstones, grinding tools, &c.	Charles Arthur	Keeseville, N. Y.	August 26, 1845
Grist-mill, percussion	Fones McCarthy	Demopolis, Ala.	February 24, 1845
Horse-power	John Haw	Hanover county, Va.	March 15, 1845
Horse-power	Richard Montgomery	Waterville, N. Y.	April 10, 1845
Horse-power, endless floor on	Luke Hale	Hollis, N. H.	January 16, 1845
Horse-power, portable	Elihu H. Jaques	Springfield, Vt.	May 16, 1845
Horse-powers, power and motion of	James Leffel	Springfield, Ohio	August 20, 1845
Mill for hulling cotton seed	Jabez Smith	Petersburg, Va.	March 15, 1845

Mill-stones, prevent from heating	Ferris Freleigh	Stowe, Ohio	March 26, 1845
Mills, wind	George Parker	Corinna, Me.	September 11, 1845

CLASS XIV.—LUMBER, INCLUDING MACHINES AND TOOLS FOR PREPARING AND MANUFACTURING, SUCH AS SAWING, PLANING, MORTISING, SHINGLE AND STAVE, CARPENTERS' AND COOPERS' IMPLEMENTS.

Augers, gimlets, &c.	William N. Clark	Chester, Ct.	January 31, 1845
Augers, handles for	Demmon C. Stone	Warwarsing, N. Y.	March 12, 1845
Barrels, &c., machine for making	William Trapp, jr.	Dryden, N. Y.	October 1, 1845
Boring machine	James B. Coffin	Mohicanville, Ohio	June 20, 1845
Boring machine	Andrew Weikart	Green Village, Ohio	November 1, 1845; antedated May 1, 1845.
Boring machine for grooves, &c.	William Wright	New York	June 10, 1845
Boring machine and mortising	Reuben D. Roys and Newell French	Detroit, Mich.	January 23, 1845
Boring and screw-cutting machine	Aretus A. Wilder	Detroit, Mich.	January 31, 1845
Lathe, turning	James D. Willowby	Gettysburg, Pa.	March 15, 1845
Lathe, turning	Milton W. St. John	Plainfield, N. Y.	May 13, 1845
Lathe, turning irregular forms	Warren Hale and Allen Goodman	Dana, Mass.	July 22, 1845
Lath, machine for cutting	Solomon F. Finch and James Wheeler	Rootstown, Ohio	August 16, 1845
Lath, machine for cutting	Samuel Cherry	Cleveland, Ohio	September 27, 1845
Mortising machine	Charles Bennett	Pepperell, Mass.	September 17, 1845
Oars, machine for turning, &c.	Ezekiel Page	Barcelona, N. Y.	December 20, 1845
Pegs, shoe, machine for making	Thomas A. Robertson	Georgetown, D. C.	August 16, 1845
Pegs, shoe, machine for making and driving	John C. Briggs	Saratoga, N. Y.	October 9, 1845
Planing machine	Reid R. Throckmorton	Brooklyn, N. Y.	May 1, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Planing machine	Benjamin Brown	Burlington, Vt.	October 9, 1845
Planing machine	Joseph E. Andrews	Boston, Mass.	November 21, 1845
Planing machine, fastening cutters	Benjamin Bucknell	Cincinnati, Ohio	March 21, 1845
Planing machine for shingles, &c.	Joseph S. L. Hunt	Boston, Mass.	October 9, 1845
Sash machine	Almon Downs	St. Clair, Mich.	November 8, 1845
Saw-mill carriages	James Dane	West Derby, Vt.	April 22, 1845
Saw-mills, self-setting	Benjamin Webb	Warren, N. Y.	April 1, 1845
Saw-mills, self-setting	Henry Quin	New Alexandria, N. J.	June 25, 1845
Sawing irregular forms	Frederick W. Harris	Lancaster, Mass.	September 27, 1845
Shave, double operating	George R. Tally	Westbrook, N. C.	April 16, 1845
Shingle machine	A. S. Pelton	Clinton, Conn.	October 16, 1845
Stave machine	John Miner and Silas Merrick	Fallstown, Pa.	November 12, 1845
Tenoning machine	James Biggs	New York	November 12, 1845

CLASS XV.—STONE AND CLAY MANUFACTURES, INCLUDING MACHINES FOR POTTERY, GLASS-MAKING, BRICK MAKING, DRESSING AND PREPARING STONE, CEMENTS, AND OTHER BUILDING MATERIALS.

Brick-making	J. Parsons Owen	Cincinnati, Ohio	July 26, 1845
Brick press	John Waite	Leicester, Mass.	March 12, 1845
Brick press	William Sanford	Cambridge, Mass.	September 9, 1845
Glass, pressing in moulds	Joseph Magoun	East Cambridge, Mass.	December 6, 1845

Grindstones. (See Mills, *Class* 14.)			
Marble polishing	J. Eckstein and H. D. Moore, assignees of Jacob Zeigler	Philadelphia, Pa.	March 12, 1845
Pottery ware, manufacture of	Joel Farnam	Stillwater, N. Y.	October 25, 1845
Stone dressing	John C. Dexter	Ionia, Mich.	March 12, 1845
Stone dressing	Jacques Keller, assignee of Daniel Pfister	Switzerland	April 10, 1845; date of foreign patent Dec. 31, 1844.

CLASS XVI.—LEATHER, INCLUDING TANNING AND DRESSING, MANUFACTURE OF BOOTS, SHOES, SADDLERY, HARNESS, ETC.

Boot crimps	Cosman White	Galway, N. Y.	February 12, 1845
Boot crimps	Starr Fairchild, assignee of Reuben Fairchild	Trumbull, Conn.	May 10, 1845
Boot crimps	Cheney Snow and T. N. Sadler	Spencer, N. Y.	May 21, 1845
Boots, machine for crimping	John Young	West Galway, N. Y.	August 26, 1845
Boots, mode of lasting	David Harrington	German Flats, N. Y.	August 26, 1845
Boot patters	Joseph Rider	Wooster, Ohio	June 2, 1845
Buckles, for harness	Kasson Frashure	Manlius, N. Y.	January 16, 1845
Buckles for harness	Kasson Frashure	Manlius, N. Y.	March 25, 1845
Harness, stuffing collars for	Thomas Wiles	Somerset, Ohio	March 21, 1845
Harness, collar for	F. C. Curtis	Columbia, S. C.	August 4, 1845
Harness, stuffing and stretching collars	Wade Haworth	Dayton, Ohio	May 7, 1845
Leather, dicing and polishing	Rufus and Henry Brackett	Boston and Woburn, Mass.	March 15, 1845
Pegging, &c. (*See class* 14.)			
Saddles	Benjamin Suits	Chittenango, N. Y.	August 9, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Saddle springs	John F. Lehr	Huntsville, Ala.	July 5, 1845
Saddle springs	Robert Caldwell	Montevallo, Ala.	May 24, 1845
Shoulder-irons, shoemakers'	James W. Newberry	Kensington, Pa.	February 20, 1845
Straps, fastening leather	Charles F. Beverly	Salem, Ohio	January 16, 1845
Tanning	Simon Snider	Dayton, Ohio	April 10, 1845
Tanning	Francis D. Parmelee	Akron, Ohio	November 1, 1845
Tanning and coloring matter	George C. Close and Edward Field	Port Chester, N. Y.	April 22, 1845

CLASS XVII.—HOUSEHOLD FURNITURE, MACHINES AND IMPLEMENTS FOR DOMESTIC PURPOSES, INCLUDING WASHING MACHINES, BREAD AND CRACKER MACHINES, FEATHER DRESSING, ETC.

Bedstead fastenings	Adin Gaunt, assignee of Ira Smith	Chagrin Falls, Ohio	October 25, 1845
Brushes, filling blocks with bristles for	Samuel Taylor Abbott R. Davis	Cambridge, Mass. Boston, Mass.	May 1, 1845
Chair, eccentric and pivot	Jordan L. Mott	New York	August 20, 1845
Cutting sausage meat	George A. Coffman	Middlebrook, Va.	February 28, 1845
Meat cutters	James M. Wilder	Peterborough, N. H.	May 10, 1845
Refrigerators	Thomas H. King	New York	June 20, 1845
Table, caloric dining	H. L. B. Lewis	New York	September 27, 1845
Tables, extension	Cornelius Briggs	Roxbury, Mass.	September 9, 1845
Washing machine	Harrison Hagans	Brandonsville, Va.	July 5, 1845

Washing machine	Benteen & Zimmerman	Petersburg, Va.	August 26, 1845
Washing machine	Horatio Hoskins	Scipio, N. Y.	August 26, 1845
Washing machine	Grey Utley	Chapel Hill, N. C.	November 26, 1845
Washing machine and churning	Harvey W. Sabine	Rushville, N. Y.	August 16, 1845
Writing-desk and table combined	John White	Marshall, Mich.	November 1, 1845; antedated July 18, 1845.

CLASS XVIII.—ARTS, POLITE, FINE, AND ORNAMENTAL, INCLUDING MUSIC, PAINTING, SCULPTURE, ENGRAVING, BOOKS, PAPER, PRINTING, BINDING, JEWELRY, ETC.

Accordeons, tuning reeds of	M. & Nicklaus Schneider	New Orleans, La.	September 27, 1845
Books, backing, machine for	William Laighton	Portsmouth, N. H.	January 10, 1845
Bugles, keyed, of turtle shell	George W. Shaw	Thompson, Conn.	August 4, 1845
Drawing, instruments for	Erastus W. Ellsworth	East Windsor, Conn.	June 7, 1845
Inkstand	Walter Hunt	New York	May 29, 1845
Inkstand	Augustus T. Arrowsmith, assig'e of Walter Hunt	New York	October 7, 1845
Inkstand	George Arrowsmith, assignee of Walter Hunt	New York	December 11, 1845
Inkstand	Daniel Harrington	Philadelphia, Pa.	November 8, 1845; antedated Sept. 2, 1845.
Piano forte	Samuel R. Warren	Montreal, Canada	July 10, 1845
Piano forte	E. L. Walker, assignee of G. W. Cherry	Carlisle, Pa. Alexandria, D. C.	January 16, 1845
Piano forte	Louis Rueckert	Baltimore, Md.	March 12, 1845
Piano forte	Charles F. Oliver, and G. W. Jackson	Lynn, Mass.	May 1, 1845

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Piano forte	Simon W. Draper	Boston, Mass.	June 20, 1845
Piano forte	Edward Badlam	Potsdam, N. Y.	October 25, 1845
Piano forte, bottoms for	William F. Senior	New York	November 21, 1845
Piano forte, Æolian attachment of reeds and mode of adjusting pitch	Charles Horst	New Orleans, Louisiana	September 27, 1845
Pen-holders	Daniel Harrington	Philadelphia, Pa.	September 2, 1845
Printing, anastatic	C. F. Baldamus & F. W. Siemans	Berlin, Prussia	October 25, 1845
Printing, electrographic	A. W. Thompson	Philadelphia, Pa.	April 26, 1845
Printing press	John L. Kingsley	New York	January 4, 1845
Printing press	John C. Kneeland	Troy, New York	February 20, 1845
Printing press	Joseph Saxton	Washington, D. C.	March 21, 1845
Printing press	Joel G. Northrup	Cortlandville, New York	April 26, 1845
Printing press	Richard M. Hoe	New York	May 1, 1845
Reeds, musical	Nathan B. Jewett	Worcester, Massachusetts	December 31, 1845
Ruling machine	Lewis Edwards	Norwich, Connecticut	October 9, 1845
Stencilling	Ezekiel B. Foster	Philadelphia, Pa.	May 13, 1845
Type-casting	David Bruce	Williamsburg, New York	June 7, 1845
Type-casting	Thomas W. Starr	Philadelphia, Pa.	August 4, 1845
Type-setting, cylindrical	Richard Hemming	Boston, Massachusetts	December 16, 1845
Writing machines	Charles Thurber	Norwich, Connecticut	November 18, 1845

CLASS XIX.—FIRE-ARMS, AND IMPLEMENTS OF WAR, AND PARTS THEREOF, INCLUDING THE MANUFACTURE OF SHOT AND GUNPOWDER.

Cannon, wrought iron	Daniel Treadwell	Cambridge, Massachusetts	February 12, 1845
Gun-locks and percussion primers	Edward Maynard	Washington, D. C.	September 22, 1845
Pistols	Ethan Allen	Norwich, Connecticut	April 16, 1845

CLASS XX.—SURGICAL AND MEDICAL INSTRUMENTS, INCLUDING TRUSSES, DENTAL INSTRUMENTS, BATHING APPARATUS, ETC.

Abdominal supporter	L. D. Fleming	Newark, New Jersey	December 31, 1845.
Baths, medicated	Benjamin Sweet	Mt. Morris, New York	December 31, 1845.
Baths, portable	Nelson Bartlett	Belvidere, Illinois	September 23, 1845.
Baths, portable shower	John Cutts Smith	Chelsea, Massachusetts	June 2, 1845.
Bathing apparatus	A. H. Reip, (assignee of W. G. Young)	Baltimore, Maryland	December 16, 1845
Bath, vapor	Thomas S. Lambert	Utica, New York	April 10, 1845
Bath, vapor	Joel H. Ross	New York	April 16, 1845
Exercising machine	James Elliott	Newark, New Jersey	September 2, 1845
Fracture apparatus	Wm. Mills & Mahlon Hoar	New Athens, Ohio	November 8, 1845
Galvanic instruments	Daniel Harrington	Philadelphia, Pa.	September 2, 1845
Galvanic rings	David C. Moorhead	New York	August 26, 1845
Nipples, artificial	Elijah Pratt	New York	August 4, 1845; antedated July 4, 1845.
Nursing bottles	Elijah Pratt	New York	August 9, 1845; antedated June 16, 1845.

K.—LIST OF PATENTS GRANTED DURING THE YEAR 1845—Continued.

Inventions or discoveries.	Patentees.	Residence.	When issued.
Swing for exercise	Joel H. Ross	New York	August 26, 1845
Teeth-setting	John Allen	Cincinnati, Ohio	December 16, 1845
Tooth-extractor	J. W. Baker & W. W. Riley	Columbus, Ohio	November 8, 1845
Truss	David B. W. Hard	Bethlehem, Connecticut	May 16, 1845
Truss, double pads	William R. Goulding	New York	July 5, 1845
Uterine supporter	Ephraim Calvin	North Granville, N. Y.	August 4, 1845
CLASS XXI.—WEARING APPAREL, ARTICLES FOR THE TOILET, ETC., INCLUDING INSTRUMENTS FOR MANUFACTURING.			
Buttons	John Hatch	Attleborough, Mass.	February 20, 1845
Garments, cutting	Sylvanus B. Stilwell	Brooklyn, New York	June 20, 1845
Hats, firemens'	James Brown	Newark, New Jersey	November 1, 1845
Hats, ventilating	George W. Cherry	Alexandria, D. C.	July 26, 1845
Tailors' measure	Abraham A. Bogardus	Newburg, New York	November 29, 1845
Tailors' measure	Allen Ward	Camden, New York	December 26, 1845

CLASS XXII.—MISCELLANEOUS.

Coal-breaker	Benjamin Haywood	Pottsville, Pa.	May 21, 1845
Coal-breaker	William Richardson	Philadelphia, Pa.	September 2, 1845
Combs, machine for dressing	Calvin R. Rogers	Saybrook, Ct.	December 20, 1845
Match splints and arranging	Asa Fessenden and Luke L. Knight	Templeton & Barre, Mass.	April 26, 1845
Seines, knitting	John D. Cornelius and James Mott	Westerly, N. Y.	May 10, 1845
Vault covers	Thaddeus Hyatt	New York	November 12, 1845

List of patents extended by act of Congress approved 4th July, 1836.

Time of renewal.	Patentees.	Inventions.	Date of patent.
February 26, 1845, (by act of Congress,) seven years from December 27, 1849	Wm. W. Woodworth, adm'r of Wm. Woodworth	Planing machine	December 27, 1828
August 21, 1845—seven years from Aug. 23, 1845	James Stimpson	Railroad plates	August 23, 1831
August 21, 1845—seven years from Aug. 23, 1845	James Stimpson	Turning short curves on railroads	August 23, 1831

Reissues of patents granted during the year 1845.

No.	Patentees.	Residence.	Inventions or discoveries.	Date of patent.	Reissued.
	Wm. W. Woodworth, adm'r of Wm. Woodworth	Hyde Park, N. Y.	Planing machine	Dec. 27, 1828	July 8, 1845
75	James Roy & Co.	Troy, N. Y.	Butt hinge	May 17, 1836	August 9, 1845
72	Ezra L. Chapman	Chester, Ct.	Auger twist	July 28, 1838	July 30, 1845
73	Philos, Eli W., and John A. Blake	New Haven, Ct.	Castors	June 30, 1838	July 30, 1845
74	Philos, Eli W., and John A. Blake	New Haven, Ct.	Castors	June 30, 1838	July 30, 1845
77	Samuel Rust	New York	Lamp wicks	May 10, 1845	August 16, 1845

Improvements added to original patents, granted during the year 1845.

No.	Patentees.	Residence.	Inventions or discoveries.	Date of patent.	Reissued.
72	Robin R. Colvin	Columbia, Pa.	Hydrant cock	- - -	January 16, 1845
73	Hezekiah Haynes	Middletown, Vt.	Rakes	- - -	Feb. 12, 1845
74	Herman Wendt	New York	Tailors' shears	- - -	June 2, 1845
75	James P. Gardner	Columbia, Tenn.	Sun dial	- - -	June 7, 1845
76	H. D. Forbes	New York	Bailing water-wheel	- - -	June 14, 1845
77	W. L. Potter	Clifton Park, N. Y.	Cooking stove	- - -	July 5, 1845

Patents granted under the act of Congress approved August 29, 1842, for seven years each.

Patentees.	Residence.	Designs.	When issued.
French, John M., assignee of Calvin Fulton	Rochester, N. Y.	Stove-plate	November 1, 1845
Hine, Charles S.	New York	Stove	May 1, 1845
Jagger, Treadwell, and Perry, assignees of Ezra Ripley	Troy, N. Y.	Ornamental stove	July 14, 1845; antedated April 1, 1845
Johnson, Geer, & Cox, assignees of Ezra Ripley	Troy, N. Y.	Stove	Oct. 16, 1845; antedated Aug. 14, 1845
Joslin Gilman	Boston, Mass.	Stand for globes, &c.	May 7, 1845
Low, Chollar, & Jones, assignees of Ezra Ripley	Troy, N. Y.	Stove	November 12, 1845
Leake, J. S. & F. S. Low, assignees of Addison Low	Albany, N. Y.	Stove	February 12, 1845
Mills, Clark	Charleston, S. C.	Bust of the Hon. J. C. Calhoun	October 7, 1845
Miller, William L.	New York	Umbrella stand	September 13, 1845
Penniman, Elijah P.	Rochester, N. Y.	Stove	September 9, 1845
Peckman, John S. & M.	Utica, N. Y.	Stove	Oct. 16, 1845; antedated Sept. 6, 1845
Ransom, Samuel H.	Albany, N. Y.	Ornamental stove	July 10, 1845
Rathbone & Co., assignees of Addison Low	Albany, N. Y.	Stove	October 7, 1945
Root, David	Cincinnati, Ohio	Stove	September 9, 1845
Starbuck, Benjamin, assignee of Anson Atwood	Troy, N. Y.	Air-tight stove	July 14, 1845
Stone, Henry	Poultney, Vt.	Stove	October 16, 1845
Slane, P. F.	East Cambridge, Mass.	Lamps	March 26, 1845

L.

Alphabetical list of patentees for the year 1845, *with their residence.*

No.	Patentees.	Residence.
4001	Ackerman, Gershom L. - -	Troy, N. Y.
4020	Allen, Oliver - - - -	Norwich, Conn.
3998	Allen, Ethan - - - -	Norwich, Conn.
4313	Allen, John - - - -	Cincinnati, Ohio.
4060	Alrichs, Jacob - - - -	Wilmington, Del.
4155	Anderson, Solomon - - -	Garrettsville, N. Y.
4281	Anderson, Alexander - - -	Paterson, N. J.
4283	Andrews, Joseph E. - - -	Boston, Mass.
3900	Andrews, John - - -	Belleville, N. J.
3927	Arndt, Jacob - - - -	Wheeling, Va.
4160	Arthur, Charles - - -	Keeseville, N. Y.
3975	Atwood, Anson - - -	Troy, N. Y.
3939	Aylesworth, Chadiah - - -	Bainbridge, N. Y.
4077	Babcock, Charles - - -	East Haddam, Conn.
4241	Badlam, Edward - - -	Potsdam, N. Y.
3989	Baker, Arnon - - -	Western, N. Y.
4261	Baker, J. W., and Wm. W. Riley -	Columbus, Ohio.
4239	Baldamus, C. F., and F. W. Siemens	Berlin, kingdom of Prussia.
3918	Ball, E. - - - -	Greentown, Ohio.
4319	Ball, Jonathan - - - -	New York.
4263	Ball, John - - - -	Greentown, Ohio.
4094	Barlow, Thomas H. - - -	Lexington, Ky.
3968	Barnum, Daniel - - -	Bridgeport, Conn.
4301	Barrow, Ebenezer - - -	New York.
4203	Barlett, Nelson - - -	Belvidere, Ill.
4215	Baxter, William - - -	Paterson, N. J.
4232	Bean, Samuel H. - - -	Philadelphia, Pa.
4311	Bebee, William - - -	New York.
4195	Bennett, Charles - - -	Pepperell, Mass.
4177	Bennett, Phineas - - -	New York.
3890	Bennett, James H. - - -	East Bennington, Vt.
4162	Benteen, J. C., and H. W. Zimmerman	Petersburg, Va.
4328	Benson, Benjamin S. - - -	Harford county, Md.
3884	Beverly, Charles F. - - -	Salem, Ohio.
3961	Bicknell, Benjamin - - -	Cincinnati, Ohio.
3925	Bigelow, Erastus B. (No. 2.) - -	Boston, Mass.
3926	Bigelow, Erastus B. (No. 3.) - -	Boston, Mass.
3987	Bigelow, Erastus B. (No. 4.) - -	Boston, Mass.
3940	Bigelow, Erastus B. (No. 5.) - -	Boston, Mass.
4022	Billings, G. W., and John Harrison -	Glasgow, Mo.
4041	Billings, G. W., and John Harrison -	Glasgow, Mo.
4071	Billings & Harrison - - -	Glasgow, Mo.
4341	Bishop, William - - -	Coventry, Conn.

L.—LIST OF PATENTEES—Continued.

No.	Patentees.	Residence.
3932	Bissell, Levi - - - -	Brooklyn, N. Y.
3943	Black, James - - - -	Williamsport, Pa.
4141	Blake, William - - -	Boston, Mass.
73	Blake, Philos, Eli W., and John A. -	New Haven, Conn.
74	Blake, Philos, Eli W., and John A. -	New Haven, Conn.
4043	Blanchard, Israel. (See *Winslow, J. F.*)	Troy, N. Y.
4135	Bliss, John, and Frederick Creighton -	New York.
4280	Bogardus, James - - -	New York.
4278	Bogardus, James - - -	New York.

M.—*List of patents expired during the year* 1845.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Adams, Charles	Boston, Mass.	Couches, sofas, chairs, &c.	April 18, 1831
Alden, Manoah, and Wm. T. Boyd	Northumberland, Pa.	Excavator and self-loading cart	July 20, 1831
Allen, Oliver	Norwich, Conn.	Rotary steam pump engine	November 18, 1831
Alley, Abijah	Cincinnati, Ohio	Bee-hive and management of bees	August 23, 1831
Allen, S. W.	Geneva, N. Y.	Double-acting cylinder pump	July 21, 1831
Aldebert, Joseph G.	Opelousas, La.	Power, &c., for propelling mills	December 29, 1831
Ambler, John, jr., and D. C.	New Berlin, N. Y.	Grist mill	June 13, 1831
Ambler, John, jr.	New Berlin, N. Y.	Mineral and soda water apparatus	June 13, 1831
Ames, D., jr., and John Ames, assignee of Sam. Eckstein	Philadelphia, Pa.	Washing rags	June 13, 1831
Ames, John	Springfield, Mass.	Washing rags	April 6, 1831
Angevine, Caleb	New York	Pendulum churn	February 28, 1831
Anthony, John	Zanesville, Ohio	Plough	February 1, 1831
Andrews, Solomon	Perth Amboy, N. J.	Gas manufacturing from oil	April 15, 1831
Andrews, Solomon	Perth Amboy, N. J.	Gas manufacturing by spirit lamps	May 5, 1831
Antes, Henry	Harrisburg, Pa.	Constructing chimneys	October 24, 1831
Anderson, John F.	Louisville, Ky.	Grist-mill	June 13, 1831
Anderson, Anson	Spencer, N. Y.	Saw-mill dogs	April 26, 1831
Appleton, James	Richmond, Va.	Washing machine	June 13, 1831
Archibald, Wiliam A.	New York	Sugar manufacturing	August 16, 1831
Anthony, David, jr.	Adams, Mass	Horse shoe	April 8, 1831
Arnold, William E.	Chatham, Conn.	Horse or animal power	May 7, 1831

Bacon, R., and William E. Marshall	Walpole, N. H.	Double ovens in chimneys	February 9, 1831
Baker, Joseph	Jefferson township, O.	Medicine	May 5, 1831
Baker, Cyrus	Charleston, N. Y.	Churn	October 6, 1831
Baker, John	Lancaster, Pa.	Draught of chimneys, &c.	October 28, 1831
Balch, William	Anne Arundel Co., Md.	Plough	October 4, 1831
Bailey, Amon	Poultney, Vt.	Churn	October 6, 1831
Barnes, Joel, and N. T. Loomis	Cornwall, Conn.	Corn-shelling	April 13, 1831
Barnes, Aaron	Deerfield, N. Y.	Manufacturing coarse salt	September 25, 1831
Barlow, Peleg	Amenia, N. Y.	Rifles for sharpening edge tools	June 13, 1831
Barlow, Peleg	Amenia, N. Y.	Sharpening edge tools	March 1, 1831
Barron, James, of U. S. N.	Philadelphia, Pa.	Filtering water and other liquids	August 30, 1831
Barron, James, (reissued)	Norfolk, Va.	Fans for bed chambers	June 13, 1831
Barber, Jesse	Sweden, N. Y.	Washing machine	August 30, 1831
Barton, James	Millford, Pa.	Spindle (cast or wrought-iron driver)	April 23, 1831
Bangs, Henry	New York	Cutting beef	April 27, 1831
Basford, Abram	New York	Cushion for billiard-tables	July 20, 1831
Bates, Eli, and D. Updegraff	Mount Pleasant, Ohio	Cooking-stove	July 20, 1831
Beals, Samuel	Mount Pleasant, Ohio	Cooking stove	October 1, 1831
Beckwith, J.	Saratoga, N. Y.	Pumps	April 6, 1831
Beach, Richard M.	Franklin, N. Y.	Boiling liquids of all kinds	April 7, 1831
Beach, Waldren	Philadelphia, Pa.	Threshing machine	November 23, 1831
Bechtler, Christopher	Ruthfordtown, N. C.	Gold washing from gravel sand	October 5, 1831
Bechtler, Christopher	Ruthfordtown, N. C.	Gold washing from sand and pounded ore	October 5, 1831
Bent, Charles, and F. Bush	Chelmsford, Mass.	Composition for stiffening hats, &c.	November 3, 1831
Belt, Rufus	Centerville, Ky.	Bedstead	February 22, 1831
Bigelow, Elisha	Georgetown, D. C.	Grist-mill	February 11, 1831
Billings, B. J., and J. S.	Gorham, N. Y.	Broom-corn, scraping	October 15, 1831
Bill, Asa G., & G. Spalding	Middletown Ct.	Loom for weaving webbing, &c.	March 28, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Bishop, Luna	Readsborough, Va.	Bellows	December 22, 1831
Blanchard, Thomas	Springfield, Mass.	Steamboat for passing rapids	March 25, 1831
Black, William	Anne Arundel co., Md.	Plough	October 4, 1831
Boston, Joseph	New York	Manufacturing gas lights, &c.	February 11, 1831
Bond, Ezra	Mendon, N. Y.	Mill for shelling and grinding corn	June 13, 1831
Bond, Ezra	Mendon, N. Y.	Corn-shelling and family mill	June 13, 1831
Bolton, John	Harrisburg, Pa.	Separating clover chaff from the straw	July 28, 1831

Boyden, Seth	Newark, N. J.	Malleable cast-iron	April 6, 1831
Brees, Ezra	Kingston, Pa.	Grist-mill	September 28, 1831
Brown, William	Mooresville, N. Y.	Tanning apparatus	November 2, 1831
Brown, John	Stonington, Ct.	Spinning cotton, &c.	June 13, 1831
Brown, John, and J. Standish	Providence and Cranston, R. I.	Throstle frame and bobbin regulator, spinning	June 13, 1831
Britton, Eben	Little Falls, N. Y.	Bee-hives and management of bees	September 9, 1831
Broughton, Peter	Charleston, S. C.	Winnowing screen, separating grain	August 5, 1831
Bryant, William, and Isaac Hiett	Davidson co., Tenn.	Railroad car	June 13, 1831
Bryent, Walter	Boston, Mass.	Coal cooking-stove	September 13, 1831
Bruff, Benjamin	Rochester, N. Y.	Raising vessels' anchors, &c.	September 13, 1831
Buck, James	Buckport, Me.	Spring catch for doors, &c.	September 28, 1831
Buel, Aaron	Caroline, N. Y.	Cordage tow-line	Decem. 29, 1831
Butterworth, John	Philadelphia co., Pa.	Bending card and can hoops	July 20, 1831
Burganzio, Eugene	New York	Tricylindric water-wheel	November 2, 1831
Bull, Mordecai	Greenwich, N. Y.	Scoop shovel	September 28, 1831

Cairon, John	New York	Distilling	January	10, 1831
Cairon, John	Boston, Mass	Distilling	August	22, 1831
Cande, G., and J. Toucey	Rochester, N. Y.	Threshing machine	April	1, 1831
Carlock, Wiliam	Baltimore, Md.	Stock (for the neck)	August	9, 1831
Carman, Luther	Oxford, Me.	Inclined friction press	April	7, 1831
Carothers, John	Shirleysburg, Pa.	Plough	Decem.	10, 1831
Carpenter, Thomas, 2d	Elmyra, N. Y.	Threshing machine	Septem.	28, 1831
Carriel, George, (reissued)	Manchester, Ct.	Cleaning rags	July	27, 1831
Casey, James R.	New York	Instituting and drawing lotteries	March	5, 1831
Catlen, J., and C. Fletcher	Cincinnati, Ohio	Rotary steam engine	June	13, 1831
Carter, George	Newark, N. J.	Steps for coaches	Novem.	26, 1831
Chase, Mark L.	Baltimore, Md.	Balancing mill-stones	June	13, 1831
Chamberlain, Samuel G.	Philadelphia, Pa.	Securing porcelain teeth	February	11, 1831
Chapman, Harvey	Corinth, N. Y.	Rolling lever carriages	March	24, 1831
Chavalier, N. W.	Baltimore, Md.	Caulking ships and other vessels	Decem.	27, 1831
Chase, Paul	New York	Combustion of anthracite coal	October	7, 1831
Church, Ambrose	Canandaigua, N. Y.	Mineral soda apparatus	July	20, 1831
Cheves, Joshua	Elmyra, N. Y.	Instituting and drawing lotteries	March	28, 1831
Clark, James	Westmoreland co., Pa.	Self-regulating conduit	January	25, 1831
Clark, Adam, jr.	Berne, N. Y.	Saw-trimmer	August	24, 1831
Clark, J., and H. Henderson, (reissued)	Baltimore, Md.	Cutting crackers	June	13, 1831
Clark, Levin	Baltimore, Md.	Railroad car, self-guiding, &c.	Septem.	28, 1831
Clibbon, Edward	Cincinnati, Ohio	House and ship furniture	Septem.	12, 1831
Coe, Elias V.	Warwick, N. Y.	Churning cream by atmospheric air	April	7, 1831
Coleman, Noah H.	Mentz, N. Y.	Mineral water, soda apparatus	July	20, 1831
Colley, John G.	Norfolk, Va.	Marine railway	September	1, 1831
Cole, John, & S. Miller	Washington co., Ohio	Barrels, &c.	Septem.	29, 1831
Conser, John G.	Rebersburg, Pa.	Dressing staves	January	31, 1831
Conser, John G.	Miles township, Pa.	Washing machine	April	21, 1831
Converse, Edward M.	Southington, Ct.	Tin plate-ware	July	20, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Cornwell, Abram	Fayette county, Ind.	Tan-yard	November 4, 1831
Coney, Martin	Portland, N. Y.	Water-wheel	April 12, 1831
Cogswell, Osmund	Cincinnati, Ohio	Tanning leather	January 29, 1831
Cook, Calvin W., (reissued)	Lowell, Mass.	Dressing wool and cotton cloth	April 23, 1831
Cooper, Peter	New York	Steam-boiler	October 13, 1831
Cooper, Isaac	Baltimore, Md.	Wheel-boxes for hubs	February 7, 1831
Cooper, Isaac	Baltimore, Md.	Reducing friction of axles, &c.	Septem. 28, 1831
Coolidge, George	Watertown, Mass.	Self-balanced hand-carts	June 13, 1831
Coston, Benton P.	Philadelphia, Pa.	Cutting meat, &c.	June 13, 1831
Cornell, Thomas J.	Randolph, Vt.	Felting and napping hats	February 11, 1831
Coulter, James	Philadelphia, Pa.	Balance for weighing canal boats and loaded wagons	October 13, 1831
Craw, Martin	Rush, N. Y.	Combined steelyards	June 13, 1831
Cram, John S.	Hanover, N. H.	Self-propelling cheese-press	December 27, 1831
Crail, Joseph	Warren, Ohio	Churn	May 5, 1831
Crawford, Ira	Sweden, N. Y.	Threshing machine	July 20, 1831
Crane, Jona	Schenectady, N. Y.	Drilling stone	June 13, 1831
Cross, Fayette	Sweden, N. Y.	Threshing machine	March 8, 1831
Cromelin, Rowland	New York	Mattresses, sofas, &c.	November 7, 1831
Currier, Ebenezer R.	Boston, Mass.	Horizontal piano forte	April 22, 1831
Cushing, Alvin D.	Troy, N. Y.	Percussion lock and walking-cane rifles, pistols, &c.	July 20, 1831
Curtis C., and T. C. Smith	Boston, Mass.	Sheaves, blocks, &c.	April 20, 1845
Cushman, N., and Isaac Loomis	White Hall, N. Y.	Boats for transporting passengers	January 8, 1845

Dart, J. W., and William Webster	Truxton, N. Y.	Water and steam power for mills, &c.	January 21, 1831
Dart, J. W., Willard, and H. Webster	Truxton, N. Y.	Grist-mill	July 20, 1831
Davis, Samuel	New York	Zinc or spelter manufacture	April 18, 1831
Davis, Samuel	New York	Zinc or spelter manufacture	August 11, 1831
Davis, jr., Shadrach	North Dartmouth, Mass.	Removing earth, &c.	February 22, 1831
Davis, Elias	Bangor, Me.	Tub or tread water-wheel	April 9, 1831
Dawkins, Johnston	Westport, Ky.	Threshing machine	November 11, 1831
Dawley, Stafford	Annesville, N. Y.	Double-toothed saw	January 14, 1831
Dawley, Augustus S.	Boston, Mass.	Splitting leather	March 22, 1831
Dawes, Isaac	Goshen farm, Md.	Tanning leather	April 21, 1831
Dean, Oliver, jr., and Joseph Woodhill	Caledonia, N. Y.	Threshing clover seed and grinding corn	April 25, 1831
Dearborn, Nathan H.	Conway, N. H.	Sawing furrow boards	December 28, 1831
Deats, John	Massillon, Ohio	Churn	August 31, 1831
Deering, J. R.	New York	Construction of ships	April 15, 1831
Deitz, John	New York	Horse-shoe	April 22, 1831
Detterich, George, and J. Conger	Tompkins co., N. Y.	Loom for weaving figured cloth	March 12, 1831
Disbrow, Levi	New York	Steam-boiler, combined furnace	February 18, 1831
Dornett, George	Boston, Mass.	Machine for cutting leather	July 20, 1831
Doty, Zuri S.	Massillon, Ohio	Churn	August 31, 1831
Douglass, John C.	New York	Safety steam-boilers	July 21, 1831
Downing, J. M.	Bristol, Pa.	Lime kiln	August 25, 1831
Dyre, T. J., and A. Richmond	New Bedford, Mass.	Candle moulds	July 20, 1831
Eastman, Joel	Bath, New Hampshire	Double chamber rotary steam engine	February 18, 1831
Eastman, Joel	Bath, New Hampshire	Steam bellows	April 8, 1831
Eastman, Joel	Bath, New Hampshire	Applying water to water-wheel	September 28, 1831
Eastman, Joel	Bath, New Hampshire	Water-wheel floats working upon hinges	February 18, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Earl, Jesse C.	Baltimore, Maryland	Truss	March 19, 1831
Eaton, Rufus	Concord, N. H.	Saw mill	November 24, 1831
Eldred, Joseph E.	Rochester, N. Y.	Level and plumb	August 25, 1331
Ellis, Elias	Duxbury, Vermont	Gathering and cleaning apples	December 6, 1831
Elliott, Moses	Boscawen, N. H.	Fanning mill	June 13, 1831
Embree, John L.	New York	Purifying whale and sperm oil	June 13, 1831
Emes, Robert	Boston, Mass.	Cleansing leather	November 21, 1831
Emes, Robert	Boston, Mass.	Polishing and diceing morocco	November 21, 1831
Emes, Robert	Boston, Mass.	Polishing and graining morocco	April 20, 1831
Emmons, Uri	New York	Music teaching, &c.	April 7, 1831
Emmons, Calvin	New York	Horse-power	August 2, 1831
Emmons, William	New York	Threshing machine	February 17, 1831
Ely, George	Clarence, New York	Jointing staves	April 14, 1831
Estes, Joel	Brownsville, Tenn.	Power-propelling mills by rolling balance wheel	August 15, 1831
Etheridge, N. G. H., and J. G. Glynn	Little Falls, N. Y.	Corn plough	July 23, 1831
Evans, Thomas, and J. Parsons	New York	Hydrostatic suspension dock	May 13, 1831
Evans, David	Philadelphia, Pa.	Fly-wheel press	August 26, 1831
Ewbank, Thomas	New York	Safety hydrostatic valve	August 27, 1831
Fahrney, Samuel	Boonsborough, Md.	Threshing machine	May 9, 1831
Fahrney, Samuel	Boonsborough, Md.	Cutting sausage meat	February 11, 1831
Fairlamb, J. P., and M. Dunot	Wilmington, Delaware	Cutting crackers	June 13, 1831

Failing, J. R., & G. Nellis	Canajoharie, N. Y.	Saw trimmer	April 27, 1831
Fairbank, E. & T., (reissued)	St. Johnsbury, Vt.	Balance for weighing heavy bodies	June 13, 1831
Fall, John S.	Rattlesnake Springs, Ga.	Cure for epilepsy and dropsy	November 3, 2831
Fay, Josiah	Hollis, New Hampshire	Cutting tenons by revolving cylinders	August 29, 1831
Fitzgerald, Daniel	New York	Cocoanut cutter	December 22, 1831
Ferrin, Otis	Lansingburg, N. Y.	Painting cloth	November 28, 1831
Fletcher, Charles	Boston, Mass.	Chemical water-proof cement	November 18, 1831
Fox, Truman, & W. G. Borland	Little Falls, N. Y.	Threshing machine	February 18, 1831
Foster, Leonard	Boston, Mass.	Mortise door fastener	February 25, 1831
Foster, A., and Wm. Avery	Salina, New York	Reacting steam engine	September 28, 1831
Foster, Willard	Owego, New York	Stump extracting	April 22, 1831
Forbes, Isaac	Bridgewater, Mass.	Jointing staves	August 3, 1831
Forbes, Samuel	New York	Steam boilers and furnaces	March 17, 1831
Fox, David	Ashtabula, Ohio	Moulding brick	August 15, 1831
Foot, Aaron	Williamstown, Mass.	Saving water-power	January 4, 1831
Freeman, Silas, jr.	New Marlborough, Mass.	Grinding apples	March 14, 1831
French, Josiah	Ware, Mass.	Spring beds	August 25, 1831
Fuller, Orlando A.	Vernon, New York	Letting boxes in wheels, &c.	December 21, 1831
Furbush, Webber	Hallowell, Maine	Washing machine	August 19, 1831
Fyler, Orsamus R.	Chelsea, Vermont	Wooden clocks	June 13, 1831
Gambel, William	Baltimore, Maryland	Bedstead	August 25, 1831
Gallup, Lewis F.	Woodstock, Vermont	Lamps, common and argand	March 9, 1831
Geoghegan, C., and James Allen, jr.	Richmond, Va.	Tobacco, manufacturing	December 6, 1831
Genung, Ira	Newark, N. J.	Cutting and punching leather	July 30, 1831
Gentry, Joseph C.	Philadelphia, Pa.	Threshing machine	March 7, 1831
Gillet, Rinaldo P.	Victor, N. Y.	Threshing machine	June 13, 1831
Giraud, John J.	Baltimore, Md.	Propelling vessels by screw	April 29, 1831
Goddard, William	Portsmouth, N. H.	Portable oven	October 12, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Goodyear, Charles	Philadelphia, Pa.	Steel-spring fork	September 7, 1831
Goodyear, Charles	Philadelphia, Pa.	Manufacturing of safe-eyed button	January 12, 1831
Gold, Stephen J.	Cornwall, Ct.	Threshing and dressing flax	January 11, 1831
Gordon, E. and D. T.	Oswego, N. Y.	Threshing machine	October 27, 1831
Gordon, Hugh	New York	Steam engine	February 28, 1831
Gorham, Abijah	Turner, Maine	Stump extracting	January 7, 1831
Gorham, William	New Orleans, La.	Excavating canals and ditches	September 5, 1831
Greathouse, William	Mason county, Ky.	Hemp-breaking	July 31, 1831
Green, C. H., and R. Montgomery	Sangerfield, N. Y.	Bark mill	Septemb'r 30, 1831
Greenleaf, Abel	Paris, N. Y.	Rotary steam engine	April 18, 1831
Greenwood, William A.	Palmer, N. Y.	Pointing pegs	February 19, 1831
Gregory, Willson	Richmond, Va.	Washing machine	September 9, 1831
Groning, Randolph	New Orleans, La.	Hair, shaving from deer-skins, &c.	October 10, 1831
Hackley, Philo M.	Herkimer, N. Y.	Boilers for steam engines	December 27, 1831
Hale, John	Hollis, N. H.	Toggle press	April 20, 1831
Hale, Luke	Hollis, N. H.	Hand printing press	December 12, 1831
Hackett, Nathan	Snow Hill, Ohio	Washing machine	August 6, 1831
Hall, John	Hollis, N. H.	Washing machine	April 20, 1831
Hand, Miles B.	Lockport, N. Y.	Washing machine	December 14, 1831
Harrington, Daniel	Philadelphia, Pa.	Ink holder	April 22, 1831
Harrington, Daniel	Philadelphia, Pa.	Exercising invalids in their rooms	April 23, 1831
Harrington, Philip	Petersburg, Pa.	Threshing machine	July 20, 1831
Harrison, George A.	New York	White lead	July 20, 1831
Harman, John, jr.	Upper Wakefield, Pa.	Threshing machine	February 11, 1831

Haslup, Rezin	Baltimore, Md.	Axletrees, hubs, &c.	February 24, 1831
Hasket, Bradbury	Boston, Mass.	Stereotype plates, blocks, &c.	March 8, 1831
Hardy, Alvah	Boston, Mass.	Shears for cutting pasteboard, &c.	August 12, 1831
Hayden, Josiah, jr.	Williamsburg, Mass.	Manufacturing flexible-shank buttons	February 17, 1831
Haywood, Levi	Phelps, N. Y.	Smut machine	April 12, 1831
Heatwoal, G.	Harrisburg, Va.	Shaving hoops	July 27, 1831
Hewitt, Thomas, jr.	Philadelphia, Pa.	Candle moulds	May 4, 1831
Hewitt, Thomas, jr.	Philadelphia, Pa.	Candle moulds	June 13, 1831
Heintzelman, John J.	Philadelphia, Pa.	Gum-elastic pad truss	July 20, 1831
Henderson, James, and C. K. Watson	Zanesville, Ohio	Measuring and cutting garments	October 22, 1831
Hidden, Enoch	New York	Percussion cannon-lock	January 14, 1831
Hidden, Enoch, as'e of S. Ringold and J. P. More	New York	Percussion cannon-lock	December 16, 1831
Hinkley, Benjamin	Fayette, Maine	Washing machine	January 31, 1831
Hinkley, Thomas	Hallowell, Maine	Cleaning chimneys	October 7, 1831
Hinkle, Charles	Lehigh county, Pa.	Elliptic carriage-springs	November 12, 1831
Hinds, Stephen	Montrose, Pa.	Composition for making beer	May 11, 1831
Hitchcock, David	New York	Corn shelling	June 13, 1831
Hetzel, Jacob, and Jesse Bevier	Ithaca, N. Y.	Threshing and shelling corn	February 14, 1831
Hobbs, Jonathan jr.,	Falmouth, Mass.	Sawing shingles	August 18, 1831
Holt, Horace	Rutland township, O.	Loom reeds	October 17, 1831
Holdridge, William	Albany, N. Y.	Drilling stone	November 10, 1831
Hooper, D. H.	New Albany, Ind.	Regulating height of water in steam-boilers	October 31, 1831
Hornback, Simon	Lafayette, Ind.	Sickles for cutting	February 11, 1831
Hortsman, William H.	Philadelphia, Pa.	Fly-nets for horses	July 28, 1831
Howard, William	Baltimore, Md.	Railroad and wagon car	April 23, 1831
Howard, Dean S.	Lyonsdale, N. Y.	Bucket for overshot water-wheel	February 16, 1831
Hoyt, William (reissued)	Vernon, Ind.	Corn shelling	June 13, 1831
Hull, Amos G. (reissued)	New York	Truss	August 17, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Hunt, Timothy	Boston, Mass.	Steamboat paddle-wheels	February 17, 1831
Hull, Alonzo G.	New York	Spring beds, elevating and depressing surface	October 1, 1831
Hurd, Merrit	Augusta, N. Y.	Grinding bark	May 3, 1831
Hurd, Merrit	Augusta, N. Y.	Cutting die-woods	July 22, 1831
Hurlbut, Stephen	Glastonbury, Conn.	Bats for hat bodies	February 14, 1831
Hurlbut, Stephen	Glastonbury, Conn.	Hardening hats on a cone	June 13, 1831
Hyde, Stephen	Williamsburg, Mass.	Oval axes	March 2, 1831
Ingham, Samuel D.	New Hope, Pa.	Canal navigation by boats, &c.	April 19, 1831
Irick, Thomas A.	Harrisburg, Va.	Brick press	July 27, 1831
Jacobs, Ruel	Wilton, N. Y.	Sawing boards	February 22, 1831
Jameson, Jacob	Springfield, Ohio	Cutting laths	August 24, 1831
Jennings, Isaiah	New York	Alcohol or spirits from grain	June 13, 1831
Jennings, Isaiah	New York	Light by liquids	June 13, 1831
Jennings, Isaiah	New York	Lamps for burning evaporable ingredients	August 1, 1831
Jennings, Isaiah	New York	Steam-boiler	December 21, 1831
Jennings, Isaiah	New York	Picture, looking-glass background	November 11, 1831
Jencks, James	Sackett's Harbor, N. Y.	Distilling	May 2, 1831
Jinkham, Samuel G.	Enfield, Mass.	Washing machine	June 13, 1831
Johnson, James	Baltimore, Md.	Life-escape and fire ladder	April 18, 1831
Joraleman, R. P., and Isaac Lockman	Northfield, N. Y.	Marine railway	April 16, 1831
Judge, John	Washington, D. C.	Hewing, dubbing, and dressing timber for ships	April 27, 1831
Judge, John	Washington, D. C.	Sticking mouldings on plank	June 13, 1831
Judson, Abel	New Lebanon, N. Y.	Gun lock	June 13, 1831

Kearsing, Thomas, H. O. Kearsing, G. T. Kearsing, and Wm. F. Kearsing	New York	Piano forte	June 13, 1831
Kemball, Philip H.	Salem, Mass.	Lever churn	June 13, 1831
Kempton, James C.	Manayunk, Pa.	Power loom	June 14, 1831
Kendall, Jonas, jr.	Watertown, Mass.	Mould for cutting butt hinges	July 21, 1831
Kendall, William	Fairfield, Maine	Applying water to saw-mills	January 12, 1831
Kendall, William	Fairfield, Maine	Water wheel	January 12, 1831
Kidder, Levi	New York	Water cistern	January 21, 1831
Kilburn, Samuel	Sterling, Mass.	Communicating motion, &c.	April 16, 1831
Kimber, Emmor	Kimborton, Pa.	Locomotive and railroad car	March 5, 1831
Kirk, Josiah W.	Schuylkill county, Pa.	Ornaments from anthracite coal	June 13, 1831
Kirkpatrick, Andrew	Urbana, Ohio	Mixing mortar	November 12, 1831
Klipstine, Philip A.	New Baltimore, Va.	Paint composition	July 20, 1831
Knight, John	Woodbury, N. J.	Scythe snath	April 7, 1831
Knight, John	Woodbury, N. J.	Rifles for sharpening scythes, &c.	April 7, 1831
Knight, Jona.	Stoddard, N. H.	Fireplaces and oven	December 15, 1831
Knowles, Hazard, (reiss'd)	Colchester, Conn.	Wood screw	April 1, 1831
Korn, Henry	Philadelphia, Pa.	Fly-nets for horses	December 8, 1831
Krauser, Samuel	Reading, Pa.	Wheels for railroad cars	November 2, 1831
Lammon, John	Macedon, N. Y.	Horse-power	December 14, 1831
Lane, Eben	Cincinnati, Ohio	Planing boards	October 26, 1831
Lane, Samuel	Hallowell, Maine	Threshing and cleaning wheat	April 6, 1831
Lange, U. B. A.	Philadelphia, Pa.	Stove for stone coal	May 3, 1831
Lester, Eben. A.	Boston, Mass.	Cotton frame gin	January 9, 1831
Linnell, Jona., jr.	Orleans, Miss.	Mixing paint	March 26, 1831
Lawrence, Wm., (reissued)	Meriden, Conn.	Chandelier	March 23, 1831
Lodge, B. F., and E. T. Cox	Zanesville, Ohio	Breaking stone	April 13, 1831
Look, Abel	Pittsfield, Mass.	Cotton gin	January 8, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Loring, Daniel	Newark, N. J.	Balance for weighing canal boats and loaded wagons	August 23, 1831
Lowe, John	Whitesborough, N. Y.	Alleviator bedstead	November 21, 1831
Luckey, James	Troy, N. Y.	Washing machine and water heating	November 19, 1831
Mackrell, William H.	Bushwick, N. Y.	Securing window blinds	June 13, 1831
Macomber, Laban L.	Gardiner, Maine	Composition for stiffening hats	January 19, 1831
Macomber, Laban L.	Gardiner, Maine	Manufacture of hats and caps	October 11, 1831
Madison, Channing	Miamisburg, Ohio	Sawing laths	April 4, 1831
Mallory, Asa, and Charles Miles	Concord, Ohio	Cast-iron, uniting with wro't-iron and steel	August 1, 1831
Mapes, James J.	New York	Tobacco-cutting knife	January 22, 1831
Marsh, Henry	Morristown, N. J.	Mortising machine	June 13, 1831
Manning, William	Plainfield, N, J.	Cutting grain	May 3, 1831
Marks, William B.	Petersburg, Va.	Threshing machine	April 8, 1831
Marvin, Dudley	Canandaigua, N. Y.	Excavating scraper	September 2, 1831
Marvin, Dudley	Canandaigua, N. Y.	Inclined-plane excavator	September 2, 1831
Marvin, Dudley	Canandaigua, N. Y.	Furnace for heating tire	January 21, 1831
Mason, Maynadier	Georgetown, D. C.	Iron borings, drillings, &c.	November 8, 1831
Maltby, Benjamin	Gates, N. Y.	Threshing machine	July 30, 1831
Matthews, Alexander	Island Creek, Ohio	Machine for hulling clover seed	December 13, 1831
Matthews, Alexander	Island Creek, Ohio	Distilling and evaporating	June 13, 1831
Mather, Jos. H.	Saybrook, Conn.	Lamps of wood	July 20, 1831
Mathies, J. L. D.	Rochester, N. Y.	Perpetual rotary ovens	December 21, 1831
Mead, William	Newburg, N. Y.	Manufacturing mineral water	April 12, 1831
Metcalf, Chandler	Hanover, N. H.	Composition for paint	February 25, 1831

Merriam, Reuben	Leicester, Mass.	Cut, prick, and set card-teeth	May 2, 1831
Messenger, James W.	Windham, Ohio	Cross-cut sawing machine	December 21, 1831
Meigs, Phineas	Madison, Conn.	Carpenter's plane	February 9, 1831
Mewhinney, Johnson	Liberty township, Ohio	Churn	July 30, 1831
McCormick, Robert, jr.	Augusta county, Va.	Self-stopping grist mill	April 20, 1831
McCormick, Robert, jr.	Augusta county, Va.	Violin and teaching	April 21, 1831
McCormick, Cyrus H.	Rockbridge county, Va.	Hill-side plough	June 13, 1831
McClung, Archibald	Fairfield, Va.	Brick press	March 26, 1831
McGrew, Alexander	Cincinnati, Ohio	Railroad and safety car	June 13, 1831
McKenney, John	West Chester, Ohio	Swing cradle	June 13, 1831
McMullen, John, and J. Hollen, jr.	Huntington county, Pa.	Knitting stockings	March 5, 1831
Michenor, Joseph	Clinton, Ohio	Applying water to water-wheel	March 9, 1831
Millis, Nicholson	New York	Manufacturing of boots and shoes	March 21, 1831
Miller, Timothy	Pittsburg, Pa.	Plough	February 13, 1831
Munroe, Dudley	Windham, N. Y.	Threshing machine	April 14, 1831
Montaudevert, James L.	Charlotte, N. C.	Gold, extracting from ore	April 30, 1831
Morgan, James	Baltimore, Md.	Loom warping	April 5, 1831
Morrison, John	Hardinsburg, Indiana	Hay press	March 12, 1831
Munch, Philip	Putnam, Ohio	Bee-hives and management of bees	July 27, 1831
Mulford, M. D.	Bloomfield, N. Y.	Washing machine	April 5, 1831
Mintzer, Peter	Philadelphia, Pa.	Fly nets for horses	July 20, 1831
Myers, Benjamin	Chambersburg, Pa.	Mill-stones	September 28, 1831
Miller, Lewis S.	Rochester, N. Y.	Cleaning burs from wool	Janury 31, 1831
Narracong, David	Skaneateles, N. Y.	Smut machine	August 18, 1831
Nicholas, Joseph	Lafourche, Louisiana	Mode of destroying insects	June 13, 1831
Newbold, T. G.	Franklin county, Va.	Curing tobacco	Janury 11, 1831
Newbury, John W.	Avon, N. Y.	Accelerating plane	November 15, 1831
Newhall, Jona.	Washington, Maine	Bevel-wheel plane	January 25, 1831
Newhall, John	Dayton, Ohio	Washing machine and press	June 13, 1831
Newsom, T. D.	Nashville, Tenn.	Power propelling machinery	January 22, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Newton, Phineas	Sidney Plains, N. Y.	Gumming saw-mill teeth	April 29, 1831
Norton, Isaac	Schuylersville, N. Y.	Threshing machine	January 6, 1831
Nunns, John F.	New York	Piano forte action	May 5, 1831
Osborne, William E.	Brighton, N. Y.	Threshing cylinder and concave	April 30, 1831
Ore, Caleb A.	Philadelphia, Pa.	Manufacturing of boots and shoes	May 5, 1831
Oram, Elizabeth	New York	Globe	January 12, 1831
Otis, Charles	Tunkhannock, Pa.	Distilling apparatus	February 16, 1831
Oxmard, Thomas	Cumberland, Maine	Sirup apparatus	August 6, 1831
Page, George	Keene, New Hampshire	Horse-power	September 28, 1831
Palmer, Nathan	New York	Window blinds	June 13, 1831
Palmer, Green B.	Pendleton, N. C.	Gold, separating from earth	April 23, 1831
Palmer, Isaac S.	Philadelphia, Pa.	Threshing machine	December 6, 1831
Palmer, James P.	Baltimore, Md.	Threshing machine	July 20, 1831
Palmeter, Phineas, jr.	Jamestown, N. Y.	Propelling wheels for boats	April 14, 1831
Parke, Larmon Z., & Iram Brewster	Schoharie, N. Y.	Cutting stone	November 10, 1831
Parker, Jabez, and H. M. Smith	Richmond, Va.	Corn shelling	April 9, 1831
Parker, William A.	Accomack county, Va.	Cure for gout and rheumatism	November 4, 1831
Parce, Ephraim, (reissued)	Lincklean, N. Y.	Potash manufacturing and leaching	July 20, 1831
Parkhurst, Aaron	Scriba, N. Y.	Mixing clay	April 14, 1831
Parkhurst, Aaron, and S. Bacon	Scriba, N. Y.	Power propelling machinery	April 11, 1831
Paterson, John	Warwick, N. Y.	Cupola blast furnace	June 13, 1831
Patridge, John	Zanesville, Ohio	Wooden ware without staves	April 16, 1831
Pawling, A.	Philadelphia, Pa.	Propelling railroad car	March 9, 1831

Payne, Philenzo, and J. Rundell	Port Gibson, Miss.	Cotton press	July 20, 1831
Peebles, Albert	Henry county, Ga.	Double plough	July 20, 1831
Percival, Jos.	Philadelphia, Pa.	Planing boards	July 20, 1831
Prescott, Joseph D.	Chesterfield, Me.	Winnowing grain	July 20, 1831
Philips, William	New Brunswick, N. J.	Horse rake	August 15, 1831
Philips, Benjamin	Philadelphia, Pa.	Paddle wheels and connecting two vessels	June 13, 1831
Phelps, Noble	Turin, N. Y.	Pumps	October 20, 1831
Phipps, J. P., and J. Holliday	Wilmington, Del.	Grist-mill	May 12, 1831
Perkins, Justus	Brutus, N. Y.	Mineral water and soda apparatus	May 3, 1831
Pierce, Nathan	Whitehall, N. Y.	Fire engine	February 23, 1831
Pine, Edward	Troy, N. Y.	Paper cutting machine	July 20, 1831
Piper, Daniel A.	Cincinnati, Ohio	Edging metal plates for roofing houses	August 16, 1831
Porter, Noah	Boston, Mass.	Grist and saw mill combined	November 17, 1831
Post, James R.	New York	Window catch and door fastening	July 21, 1831
Powell, John	Salisbury, N. C.	Gold ores and alluvial auriferous earth washing	April 1, 1831
Prince, John	New York	Inking distributer	December 3, 1831
Pudney, John	Waterford, N. Y.	Marking and cutting garments	September 3, 1831
Pulsifer, John S. and Ebenezer	Ipswich, Mass.	Cheese press	February 14, 1831
Prescott, William	Pottsville, Pa.	Threshing machine	October 25, 1831
Reading, Pierson	Trenton, N. J.	Clover mill	October 25, 1831
Reed, Jesse	Marshfield, Mass.	Corn shelling	September 1, 1831
Reed, Jesse	Marshfield, Mass.	Furnaces for generating steam	January 5, 1831
Reed, Jesse	Marshfield, Mass.	Pumps	August 5, 1731
Reed, Cheney	Worcester, Mass.	Manufacturing shingles	September 28, 1831
Reese, Thomas	Baltimore, Md.	Winnowing grain	July 20, 1831
Redifer, Jacob	Philadelphia, Pa.	Threshing machine	July 25, 1831
Reekers, John J.	Baltimore, Md.	Reducing friction	June 13, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Reilly, Boyd	Cincinnati, Ohio	Steam bath, applying	February 5, 1831
Renoir, Alexander	New Orleans, La.	Propelling boats by man-power	July 20, 1831
Revere, John	Boston, Mass.	Metallic composition for sheathing vessels	March 24, 1831
Rice, Levi	Milburn, Mass.	Spinning cotton and wool	November 14, 1831
Richards, Spencer	Cambridge, Mass.	Glass knobs	October 31, 1831
Richards, George H.	Washington, D. C.	Caouchouc fluid	April 11, 1831
Richards, Jedediah	Elbridge, N. Y.	Punching iron and steel	Septem. 28, 1831
Richardson, J. S.	New Market, N. H.	Self acting fire alarm	August 15, 1831
Richardson, J. S.	New Market, N. H.	Steam engine	October 17, 1831
Richardson, Alpha	Boston, Mass.	Splitting leather	April 23, 1831
Richison, Andrew	Newcastle, Ohio	Threshing machine	April 22, 1831
Richmond, Ch., and Saml. Caswell, jr.	Taunton, Mass.	Spades and shovels	April 7, 1831
Robinson, Henry	Boston, Mass.	Gas meters	March 10, 1831
Robbins, J. N.	Troy, Mo.	Parturient invalid bedstead	October 20, 1831
Roe, Stephen C.	New York	Conical stove	March 3, 1831
Rogers, Samuel	Ashville, N. C.	Threshing machine for rice	July 25, 1831
Ross, Tallmage	Pickaway, Ohio	Churn, and working it	January 26, 1831
Rugg, Samuel	Lancaster, Mass.	Revolving harrow	January 11, 1831
Rutherford, Ira W.	Albany, N. Y.	Vertical tooth-extractor	January 4, 1831
Sample, William P.	Bedford county, Tenn.	Cotton-cultivating harrow and scraper	September 3, 1831
Savage, William, and H. Davidson	Horsewell, Ky.	Plough	August 24, 1831
Seger, James S.	New York	Balance weighing machine	July 20, 1831
Seeley, Oran W.	Williamson, N. Y.	Mortar for brick	July 20, 1831

Silliman, Levi	Albany, N. Y.	Preventing chimneys from smoking	July 20, 1831
Sites, John	Harrisburg, Va.	Brick press	March 29, 1831
Sizer, Amasa	Cheshire, Conn.	Coffee and spice mill	December 22, 1831
Scott, John	Philadelphia, Pa.	Glass frames for pictures	April 6, 1831
Shaw, Oliver H.	Richmond, Va.	Art of teaching arithmetic	April 16, 1831
Shaw, Erastus, and R. H. Burke	Canton, Conn.	Axes	November 3, 1831
Sherman, Anson	New York	Printing press	February 26, 1831
Sherman, Levi	Bridgeport, Conn.	Saddle	January 18, 1831
Sherman, Thos. H.	Hastings, N. Y.	Potash manufacturing	February 2, 1831
Sherr, E. N.	Philadelphia, Pa.	Guitar	October 6, 1831
Shugert, John	Pittsburg, Pa.	Punching copper and brass	July 20, 1831
Shepardson, Daniel	Hamilton, N. Y.	Tire and hoop bending	February 7, 1831
Shelter, George	York, Pa.	Screw auger	March 21, 1831
Shull, John	New Petersburg, Ohio	Washing machine	August 19, 1831
Shaffer, Philip	Richmond towns'p, Pa.	Threshing machine	November 16, 1831
Shulz, J. W., and Joel Truel	Medford, Mass.	Construction of lamps	March 19, 1831
Skinner, Elijah	Sandwich, N. H.	Mantels for fireplaces	July 20, 1831
Skinner, Elijah, and John Webster	Sandwich, N. H.	Vertical lath mill	August 26, 1831
Smith, Jacamiah	Morris, N. J.	Saw mill	January 27, 1831
Smith, Lewis T. C.	Scott county, Ky.	Horse shoe	December 15, 1831
Smith, David	Emmetsburg, Md.	Churn	April 21, 1831
Smith, P., and T. H. Arnold	Haddam, Conn.	Corn seeding, &c.	January 21, 1831
Smith, Alonzo L.	Weedsport, N. Y.	Threshing, shelling corn, and grinding apples	April 27, 1831
Smith, Alonzo L.	Brutus, N. Y.	Mineral-water and soda apparatus	June 13, 1831
Sower, Brook W.	Leesburg, Va.	Quilting frame	December 23, 1831
Spencer, Joseph	Canajoharie, N. Y.	Saw, gumming and trimming	August 15, 1831

M.—LIST OF EXPIRED PATENTS—Continued.

Names of patentees.	Residence.	Inventions or discoveries.	Date of patent.
Squires, William H., and Coral C. White	Ledyard, N. Y.	Inclined water-wheel	February 5, 1831
Stimpson, James	Baltimore, Md.	Inclined planes	August 23, 1831
Stimpson, James	Baltimore, Md.	Railroad switches	August 23, 1831
Stimpson, James	Baltimore, Md.	Railroad turn-about	August 23, 1831
Stimpson, James	Baltimore, Md.	Railroad carriages	August 23, 1831
Spencer, Henry	Maryland, N. Y.	Machine for threshing and cleaning smut	November 7, 1831

N.

CLAIMS OF PATENTS ISSUED DURING 1845.

No. 3873.

What I claim as my invention, and desire to secure by letters patent, is the combination of levers K K with the side links P P, with chains Q Q passing over rollers R R, having vertical links to support the movable platen E E. I also claim the invention of the arrangement for connecting the self-adjusting platen to the machinery, by which the power is applied to the press; so that whenever it takes beyond a limited amount of power to propel the press, the simple action of the power in propelling the press will release the bale until only the given amount of power is required.

And I also claim the invention of the arrangement for connecting the above arrangement for adjusting the power upon the bale to the movable platen of the press, substantially in the manner and for the purposes set forth.

WM. BULLOCK.

No. 3874.

Having thus fully described the nature of my invention, and shown the whole construction and operation of my machine, what I claim therein as new, and desire to secure by letters patent, is the arrangement of the gripers, combined with the carrying belts, by which I am enabled to carry in the paper, hold it, retain it until it is perfected, by being printed on both sides, and then deposite it; these operations being effected by so combining the sheet-apparatus with the inking rollers as to give to the carrying belts and gripers an intermitting progressive movement, as described.

I also claim, in combination with the printing apparatus, the so arranging of the carrying belts as to return the sheets of paper which have been printed on one side at nearly the same level which they occupied when they received the first impression, they being in both cases at the proper elevation for giving the impression as described.

I claim likewise the manner in which the grippers are made to open and close by means of a spring, operating like that marked *f*, to force and hold them open, and a bolt for holding them when closed, in combination with the closer and opener, substantially as set forth.

J. L. KINGSLEY.

No. 3875.

Having thus described my improvement and its advantages, I now claim as my invention, and desire to secure by letters patent, the combination of a cylinder brush, having fans on the end thereof, with a cotton-gin, for purposes and in the manner herein set forth, or in any manner substantially the same.

ELEAZER CARVER.

No. 3876.

Having thus fully described the manner in which I construct my coal-burner, and shown its operation as resulting from the particular combination of its respective parts, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have combined and arranged the two stories thereof, consisting of two cylinders, with the eight triangular, radiating flues arranged around and in contact with them; said flues communicating with the flue space in the plinth, with intermediate chamber, and with the cornice space, as described; the two latter being divided by partitions into anterior and posterior portions, in the manner and for the purpose set forth; and there being also openings, such as are herein described and represented, through the upper end of the upper cylinder into the cornice space, in the manner and for the purpose above made known; it being distinctly understood that I do not make any claim to either of the individual parts, taken separately and alone, but that I limit my claim to the combination and arrangement thereof as a whole; not intendng, however, by this claim, to confine myself, in constructing my stove, to the particular form of the respective parts, as described and represented, but to vary these as I may deem expedient, whilst I attain the same end by means substantially the same.

HENRY STANLEY.

No. 3877.

What I claim as my invention, and desire to secure by letters patent, is, the two horizontal flues *o* in combination with the oven, their bottom plates forming part of the top of the oven; their inner plates forming partly two sides of the same; their top plates being formed by the hearth plate F, and their outside plates by the side plates B and B of the stove. I do not claim, merely, to conduct the heat all round the oven, but I do claim the peculiar arrangement of the flues to effect the said object, as hereinabove described.

CHARLES WOLF.

No. 3878.

Having thus fully described the nature of my improvements in the vibrating cylinder steam engine, and shown the operation thereof, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged the same, so as to connect two piston rods, proceeding from one piston, to two driving shafts, for the purpose of turning them simultaneously in opposite directions, as set forth.

I likewise claim, in combination with the two piston rods, the connecting of one of them to one of the crank pins by means of a link or equivalent device, allowing of the amount of lateral motion necessary to enable both the cranks to revolve with perfect freedom.

I do not claim the passing of two piston rods through the two heads of a piston as in itself new, this having been previously done; but I limit my claim to the combination and arrangement by which I effect the object that it was the purpose of this invention to accomplish, as set forth, and applied to the vibrating cylinder steam engine.

J. H. TOWNE.

No. 3879.

The invention claimed and desired to be secured by letters patent, is the combination of the apparatus for dropping or planting potatoes with the apparatus for ploughing the ground, opening the drills, and covering the seed, as described.

ENOCH WOODS.

No. 3880.

Having thus fully described the nature and construction of my machine for backing books in the process of binding, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of causing the backs of such books to be carried along against a fluted roller, or a block of metal, whilst they are confined between the jaws of what I have herein denominated the backing irons; the respective parts of said machine being arranged and operating substantially as herein fully made known.

WILLIAM LAIGHTON.

No. 3881.

My invention, and therefore what I claim, consists in the manner in which I effect the drying of the sized bat without the employment, in the drying apartment, of chain aprons or conveyors, such as are generally used therein, viz: By means of the long vertical apartments, S, (for the reception of the bat and hot air,) and (in combination with) a passage or flue, *a*, (for the discharge of the air in a current) proceeding from the upper part thereof; the same being arranged with respect to the size rollers, and the bat being carried through the said passage and into the hot air apartment, and out of the latter through a passage (*b*) or outlet, and received and wound upon a beam, substantially as herein before set forth.

In testimony whereof, I have hereunto set my signature this third day of December, A. D. 1844.

OLIVER FENNY.

No. 3882.

Having thus fully described the manner in which I construct my vertical forge-hammer apparatus, and shown the operation of the respective parts thereof, what I claim therein as new, and desire to secure by letters patent, is the manner of operating upon the lifting rod, by means of the friction drums, one of which is made to advance to and recede therefrom by being placed on a sliding frame, which is operated upon by a toggle joint, under an arrangement of parts substantially the same with that herein described.

I also claim the manner of arranging the respective levers O and P, the catch *d*, the cam wheels M, and their appendages, so as to be operated upon by the lines and chain attached to the said levers, substantially as herein fully made known.

And I do hereby declare that I do not intend by these claims to limit myself to the precise form and deposition of the respective parts of said

machine, but to vary these as I may think proper, whilst I attain the same end by equivalent means.

GEO. ESCOL SELLERS.

No. 3883.

What I claim as my invention, and desire to secure by letters patent, is the construction and use, for all similar purposes with other buckles, of the following parts of my angular box, and grooved roller buckle, to wit: Said *grooved roller* moving upon the *grooved surface* of the back section of the angular box, and the manner of its attachment to said back section by means of a *loop* or *ring*, and a *slide*, so that the same retain its place, and act upon the strap required to be held by pressing it against the *bridge* or front section of said angular box, and any and everything essentially the same; all other parts of said buckle being disclaimed as like or similar to those of other buckles now in common use.

KASSON FRASHURE.

No. 3884.

What I claim as my invention, and which I desire to secure by letters patent, is the before described method of fastening together the ends of straps and other articles by a combined hinged convex lever, and serrated plate, and adjustable sliding bar, whether constructed and arranged in the manner set forth, or other mode substantially the same.

CHARLES F. BEVERLY.

No. 3885.

What I claim and desire to secure by letters patent, is the arrangement of the sectors and double rack piston rod in combination with the follower of the press, by means of the connecting rods, to adapt the movement of the platen or follower to the increased resistance of the cotton, and thus attain the greatest amount of effect with the least expenditure of power, as described.

PHILOS B. TYLER.

No. 3886.

What I claim as my invention, and which I desire to secure by letters patent, is the manner in which I construct my water-wheel; that is to say, the form of the buckets having two distinct curves; one of the curves projecting beyond the periphery of the wheel into spiral shutes, the curves on the face and back of the buckets corresponding; and in combination therewith, the openings in the bottom of the spiral shútes for the discharge of the water.

JAMES GARDNER.

No. 3887.

Having thus set forth my invention, I shall claim the mode of firmly uniting together, by one screw bolt, the several parts of the three links (B,

C, C,) and the floor-board, viz: by a combination of ears (*d*, *e*,) cast upon the inner sides of the two portions of the link B, so as to lap over each other, and permit the screw-bolt to pass through them, and operate upon and with respect to the several parts, as described.

In testimony whereof, I have hereunto set my signature, this third day of December, A. D. 1844.

LUKE HALE.

No. 3888.

Having thus fully described the improvements, what we claim therein as new, and desire to secure by letters patent, is an extra set of hammers, weights, or dampers, or a continuous bearing, constructed and arranged as herein described; passing over the centres of the strings of a piano forte, so as to be brought down upon them by a pedal or other analogous device, for the purpose of producing the harmonious tones, as herein set forth.

E. L. WALKER,
G. W. CHERRY.

No. 3889.

I am aware that cast-iron base rails have been capped with wrought-iron rails, and therefore I do not claim this as my invention; but what I do claim as new, and desire to secure by letters patent, is connecting the cap rails with the base rails, by means of a fillet, flanch, or rebate, as herein described, so that, by breaking joints, the base and cap rails will be retained in their proper lines at the joints, and the cap rail may be extended up to or beyond the inner edge of the base rail, and thus prevent the flanches of the wheels from acting against the base rail, as described.

WM. M. C. CUSHMAN.

No. 3890.

Now, what I claim as my invention, and desire to secure by letters patent, is the manner of grasping the standing flax, for the purpose of pulling it, between the fingers or jaws, by means of the movable part sliding in the clamps and receiving its motion in the direction of the handles from the crank-knob, by means of a slot and pin, or toggle joint, as above set forth and described.

JAMES H. BENNET.

No. 3891.

Having thus fully described our machine, what we claim therein as new, and desire to secure by letters patent, are as follows, to wit: We claim the combination in the mandrel of a rotary motion for the purposes of boring and drilling, with a vertical motion for the purpose of mortising; the mandrel taking both motions in the former operations, and the vertical only in the latter.

REUBEN D. ROYS,
NEWELL FRENCH.

No. 3892.

Having thus fully described our improvement, we wish it to be understood that we do not claim, as our invention, combining the bowl of a lamp with the stem thereof, by blowing it on, as that has before been done; but what we do claim is combining the mould for the bowl of the lamp, constructed substantially as herein before set forth, with the horizontal shelf *d*, (into which the top of the foot of the lamp is fitted,) and the platform *a*, *a*, on which said foot rests, by which the connexion or cementing of the bowl and foot is accomplished in a truer and more perfect manner than it can otherwise be done; the whole arrangement being substantially as herein before specified.

In testimony that the foregoing is a true description of our said invention and improvement, we have hereunto set our signatures, this second day of May, in the year eighteen hundred and forty-four.

P. F. SLANE,
JOHN GOLDING.

No. 3893.

What we claim as our invention or improvement, and desire to secure by letters patent, is as follows: 1. In the machine for paring the head of the screw, we claim as our invention or improvement the combination of the two levers (C and K) with the spring (*r*,) by which the blank is removed from the jaws of the spindle after the paring of the head is completed, as above described and set forth.

2. In the machine for nicking or scoring the screw, we claim as our invention the lever (*e*) to which the face-plate *(f)* is attached, in combination with the lever (*o*) and trip-lever, (*h*,) for the purpose and in the manner described; and these, thus combined, we also claim in combination with the lever (H) for re-engaging the trip lever, (*h*,) as described.

3. In the machine for threading the screw, we claim as our invention or improvement the manner of combining the gauge (12) that operates the slide (22) with the spindle, by means of the lever and lifting rod, (3,) in manner substantially as described.

SIMEON BROOKS,
WILLIAM N. CLARK.

No. 3894.

Having thus fully described my inventions, what I claim therein as new, and for which I desire to secure letters patent, is—

1st. I claim the method of introducing the resin, or fat, into the retort, by means of the feeder G, and pipe H, and tube H′, as above described, directly on to the coke or other charge in the retort, whereby the disadvantages arising from the collection of sediment in the ordinary syphon tube are obviated, and the resin or oil is introduced into the hottest part of the retort without any portion coming in contact with the sides.

2d. I claim the jacket around the pipe J, that conveys the gas to the condenser, in combination with the cistern of the gasometer, in the manner and for the purpose described; thus keeping the pipe J cool, and preventing the tar from baking on to said pipe.

3d. I claim the combination of a condenser, constructed and arranged as above made known, with the retort and gasometer, for the purposes herein specified, to condense the gas that passes through it, and having a cistern below to draw the tar into.

4th. I claim constructing the gas burner in the manner described, and having a long double tube, with a conical chamber above it, as herein specified, so as to heat the gas to a high temperature before burning.

Lastly, I claim the mercurial joint, constructed and arranged substantially as set forth for passing gas from a stationary to a revolving pipe, as herein before explained.

BEN. F. COSTON.

No. 3895.

I claim, 1st, the curved (or angled downward, for the purpose described) bearer, for supporting the blade, in the manner described.

2d. I claim the reversed angle of the teeth of the blade, in manner described.

3d. I claim the arrangement and construction of the fingers, (or teeth for supporting the grain,) so as to form the angular spaces in front of the blade, *a s*, and for the purpose described.

4th. I claim the combination of the bow L, and dividing iron M, for separating the wheat, in the way described.

5th. I claim setting the lower end of the reel post R behind the blade, curving it at R, and leaning it forward at top, thereby favoring the cutting and enabling me to brace it at top by the front brace S, as described, which I claim in combination with the post.

CYRUS H. McCORMICK.

No. 3896.

What we claim as our discovery, and desire to have secured by letters patent, is the composition or compound metal formed by the admixture of the above specified proportions of *zinc* and of the "*hardening*" composition above described, whether tin be *superadded* in the proportions stated or not.

INCREASE S. HILL,
JOSEPH DIXON.

No. 3897.

Having thus fully described my improvement, what I claim as my invention, and desire to secure by letters patent, is the combination of the lever (J) and dogs (K and I) with the nut G, and shaft, (L) for stopping the nut and throwing the wheel (T) out of gear, as herein set forth.

ARETUS A. WILDER.

No. 3898.

Having thus fully described the nature of my improvements on my plough, and shown how the same are carried into operation, what I claim therein as new is the manner in which I have given stability to the respective parts of my plough, by securing the same together by the means herein

set forth; that is to say, by the combination of the staple and wedge D and *c*, of the projections *e e*, on the point of the hooked knob *f*, and its wedge *h*, arranged and connected with the other parts as set forth, by which arrangement and connexion of the respective parts I leave those parts which are to bear the main strain and shocks in a form which insures the necessary strength and prevents them from moving out of their places.

I do not pretend to claim the use of hooks, mortises, or wedges, as such, but limit my claim, as above set forth, to the particular manner in which I have arranged these in my improved plough.

BANCROFT WOODCOCK.

No. 3899.

What I claim as my improvement, and desire to secure by letters patent, is the mode of making the single twist ship auger, the bit and gimlet, with the upper inner surface A of the twist, *concave*, as above described, and for the object set forth.

WILLIAM N. CLARK.

No. 3900.

Having thus fully described the nature of my improvements in the machinery or apparatus for manufacturing cloth by felting, and shown the manner in which the same operates, what I claim therein as new, and desire to secure by letters patent, is the manner herein described and represented of combining and arranging the steam box H, with its perforated top, the second steam box H′ in the rear thereof, and the reciprocating platen or rubber by which it is surmounted, so as to co-operate in the process of felting, in the manner herein set forth.

It will be manifest that a single steam box might be made to answer the purpose of the two, but the two are preferred as being less cumbrous, more easily made, and answering the purpose better than one of double size.

JOHN ANDREWS.

No. 3901.

Having thus fully described my improvements, I wish it to be understood that I do not claim a cultivator with the side beams of the frame movable, nor do I claim the spreading or contracting seed planters, or the extension of shafts, as described in my machine, as it has been before used for various purposes; but what I do claim as my invention, and desire to secure by letters pattent, is the arrangement of the ploughs, as herein described, by means of the curved side pieces of the frame; said side pieces being made so that they can be expanded for the purposes herein set forth.

I also claim, in combination with the above, the shaft *m*, constructed so as to extend as herein described, combined with and operating the slides in the hoppers. I further claim the construction of the lock of the plough as herein described, so as to fasten all of the parts by hooking the land side into the cutter, as described.

R. H. SPRINGSTEED.

No. 3902.

Having thus fully described my invention, and the operation of the same, I would remark that I do not claim applying heat to the surface of the brine for the purposes of crystalizing the salt, as that has before been done; but I confine my claim to the mode herein described of applying the heat to the surface of the brine as that surface rises or falls, by means of the revolving or floating pipe *b*, constructed and operating substantially as herein described. Its advantages are two fold. First, preserves a low degree of heat in all parts of the cistern. Second, is a convenient mode of preventing the currents in the lower strata of brine.

J. S. O. BROOKS.

No. 3903.

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the bolt or pin E, in combination with the wings D, and perforated segments G G 2, and plate L, on one-half of the hinge, or on the shutter, by which means the shutter or blind can be fastened and held in any position corresponding with the holes or wings, as described.

R. B. VARDEN.

No. 3904.

What I claim as my invention is the dispensing with the main cylinder of the common carding machine, by so disposing of the licker in and workers and strippers around the lower part of the circumference of the doffer, and giving them such motion, as to deliver to and receive from the doffer itself without the aid of the main cylinder.

HUGH WIGHTMAN.

No. 3906.

What I claim as my invention, in the foregoing specification, is this, viz: I have invented a new and improved kind of cannon, which is formed of a series of rings, or short hollow cylinders, joined together by their ends in sufficient number to form the length required for the cannon, and for this I claim letters patent.

DANIEL TREADWELL.

No. 3907.

What I claim as our invention, and desire to secure by letters patent, is the mode of operating the brake by means of the body sliding on the frame, and connected with the levers of the brake, in combination with the mode of removing the brake from the wheels by connecting it with the swingletree, substantially as herein described.

DAVID D. GIBSON.
WALKER COBBS.

No. 3908.

Having thus fully described my improvements in grinding corn and cobs, &c., I wish it to be understood that I do not claim the cutting or breaking

of the same, as that has before been done by knives or other similar apparatus; but what I do claim as my invention, and which I desire to secure by letters patent, is the inclined recess outside the inclined plane, and the end of the shoulder, constructed in the manner and for the purpose herein set forth; and in combination therewith I claim the recess in the runner on one side of the eye of the stone, as above described.

E. A. KNOWLTON.

No. 3909.

What I claim as my invention, and which I desire to secure by letters patent, is the construction of the two hinged gripers for holding the ends of the leather whilst straining it—that is to say, being made with openings in the lower ends of the gripers, beveled on the inside, or wider on the outer than on the inner face, into which are fitted loosely hinged shutters of corresponding size and shape, between which and the griper the end of the leather is griped, a projection or cog being formed on the lower end of each griper, that runs back and forth in the horizontal grooves in the plates in the head of the jaws; the upper ends of the gripers being hinged to the horizontal connecting bar containing the female screw, into which is screwed the vertical male screw, passing through the top of the sliding frame. I also claim constructing the jaws with the channeled plates, in the manner and for the purpose set forth.

COSMAN WHITE.

No. 3910.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the oven and fire box—that is, the fire box being surrounded with an air chamber, perforated through the top plate with holes communicating with the oven, the oven being directly over the fire box, and the smoke pipe ascending through the oven, and the flame and smoke being distributed over the top of the oven in the manner described; these features, in combination, constituting the economy of my summer baker. The whole arrangement and combination being substantially as herein set forth.

JOHN T. DAVY.

No. 3911.

What I claim as my invention, and which I desire to secure by letters patent, is the arrangement of the horizontal parallel tubes and slides, and the manner of dividing the bees by means of the breath, as set forth.

ELIAS JONES.

No. 3912.

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the revolving whipper with the endless conveyor, arranged and operated in the manner and for the purpose set forth.

FONES McCARTHY.

No. 3913.

Having thus fully described my plough, what I claim therein as my invention, and desire to secure by letters patent, is the combination of the stubble bit with the land side casting, in the manner and for the purpose herein set forth.

SETH J. ROBERTS.

No. 3914.

What I claim as my invention, and which I desire to secure by letters patent, is—

1st. The arrangement of the horizontal bars, crossed levers, and jaws, with the female screw formed therein, in combination with the catch to stop the hammer, and horizontal screw shaft, as described.

2d. The arrangement of the triangular wire rod and wire-hooked rods, passing through slots made in the hammer handle, in the manner and for the purpose described, in combination with the stock or frame upright piece of iron spiral or other springs, for holding the tool in the required position, as described.

3d. The mode of lessening the force of the blow of the hammer as the point of the file approaches the tool, by means of the forked bar, secured to the upright attached to one end of the frame, coming in contact with the transverse board secured to the end of the wedge, as the front of the file approaches the tool, and forcing said wedge forward, which causes the spiral spring to raise on the upright pin, as described.

4th. The mode of increasing the effect of the blow of the hammer, by pushing down the inclined slide, which acts on the end of the piece of timber and raises the upright, and causes the end of the hammer-handle, in its descent, to come in contact with the pin resting on the spiral spring, which depresses said spring; and when the handle is disengaged from the tappits on the wheel, the spring, pressing on the under side of the handle, forces it upward, and thus adds to the force of the blow of the hammer.

SOLOMON WHIPPLE.

No. 3915.

I do not claim the making what is termed a pantaloon button, in two pieces of metallic plate, held together by the edge of one being turned over upon that of the other, nor do I claim the combination of the two plates (so applied to each other) with a circular or other proper shaped piece of wood, or cloth, or woven material, interposed between them; neither do I claim the combination of a plate of metal and a circular disc of wood together—the former being confined to the latter by its edges being lapped over and pressed down upon those of the latter; but that which I do claim is my improvement in the modes usually adopted for forming or making the eylet-holes or thread-passages of buttons, composed of two circular plates of metal, the one of said pieces being confined to the other, as above described; the said improvement consisting in punching holes through the plates (so as to leave a burr projecting on one side of the plate from each hole) before they are applied and connected to each other, and (in combination with) applying the said holes of one plate to those of the other in such manner that

their burred projecting edges may be in direct contact, and the counter sunk portion of each of the holes of the plate (there being the same number of holes in each plate) be opposite to that of the corresponding hole of the other plate, thereby forming eylets or passages counter-sunk on *both sides* of the *button;* by which mode of constructing the above, the wear of the threads which secure the button when sewed to cloth or other material is to a very great degree obviated; the whole being substantially as above described.

JOHN HATCH.

No. 3916.

I claim as my invention, and desire to secure by letters patent, the manner in which I have constructed my shoulder-iron, by the combination of the two portions, essentially in the manner described—the distance of these two parts being regulated substantially in the manner set forth.

JAMES W. NEWBERY.

No. 3917.

Having thus fully described the nature of my improvements in the printing-press, what I claim as new therein, and desire to secure by letters patent, is the manner in which I combine, arrange, and operate the apparatus for governing the motion of the sheet on which the impression is to be made—said apparatus consisting of the sliding catch, the wheels, the cam, and the catch; these parts being arranged and operating substantially as described.

J. C. KNEELAND.

No. 3918.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the coulter, the land-side, and the self-sharpening point, so that the three may be secured together by two bolts, giving, at the same time, great strength to these, as herein above described.

E. BALL.

No. 3919.

What I claim, and desire to secure by letters patent as my invention, is, 1st. The combination of a set of flues and dampers, as above described, between two horizontal plates, for the purpose of drawing the flame and heated air around and about the boilers or kettles, as herein set forth, by which I admit the flame and heated air through the lower horizontal plate into the flues above named, at one side or portion of the boiler apertures, thereby obliging the draught first to cross the bottoms of the boilers or kettles, and then through the apertures in the horizontal plate; thence around the boilers or kettles, through the flues, to the flues to the pipe.

2d. I claim the combination and arrangement of the cylinder for burning coal with the plates, in the manner and for the purpose above described.

ROBERT WILSON.

No. 3920.

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the lever with which its click and ratchet-wheel, in combination with the pins or studs upon the cutter-gate, by which I regulate the length of the feed, and at the same time insure the operation of the pins upon the click; all of which being arranged, constructed, and operates as herein above described.

D. M. SECHLER.

No. 3921.

What I claim as my invention, and desire to secure by letters patent, is the application of the difference in the expansion of two metals, or the expansion of a metal, as a means of preventing explosions of steam-boilers, in the manner described, or any analogous means producing the same result or effect.

C. EVANS.

No. 3922.

Having thus fully described the nature of my improvement in the manner of applying the hot blast to the bloomery forge-fire, I do hereby declare that I do not make any claim to the applying of the hot blast thereto, nor do I make any claim to the form or combination of the pipes for heating the air—this being the same with numerous others which have been long known and used; but what I do claim as of my invention, and desire to secure by letters patent, is the manner in which I have combined said pipes with the bloomery forge-fire, by placing them within the chimney immediately over said fire; which chimney is formed in the manner herein described and represented, so as to effect the desired object without the use of an arch or of any analogous structure. To this particular combination and arrangement I limit my claim.

PAUL A. SABBATON.

No. 3923.

1. What I claim as my invention is the mode of liberating and reclosing the valves in combination with the expansion-tube and rod, (the rod being hermetically attached to the inner end of the tube,) by which arrangement a stuffing-box, for establishing the connexion between the inside and outside of the boiler, is dispensed with, as described.

2. What I also claim is, so connecting the safety-valves with the expansion-rods as to reclose the valve by the contraction of the metal after a given quantity of steam has blown off, as described.

WM. M. WRIGHT.

No. 3924.

What I claim as my invention, and which I desire to secure by letters patent, is the construction of the bed in which the grain is ground, and through which it is discharged when ground to the degree of fineness re-

quired; that is to say, constructing the centre with a longitudinal, semicircular, or other concave depression, in combination with the sides, flaring outward and upward, forming the inclined planes, which are perforated with apertures of the size to which the grain is to be reduced, and through which the grain is discharged when thus reduced; said inclined sides serving, also, the purpose of conductors of the grain to the bed, as guards to prevent its escape therefrom, in combination with the pounders, as herein described.

FONES McCARTHY.

No. 3925.

Having thus fully described my improved temple, what I claim therein as my invention, and desire to secure by letters patent, is having the movable jaw at one end, and the lever by which it is operated at the other end of the rod, and near to the joint which connects the bar to the beam, in combination with the long bar jointed to the breast-beam, so as to act when there is little or no motion; by which the operation is rendered more effective, and the free action of the temple unimpeded and more certain.

E. B. BIGELOW.

No. 3926.

Having thus described my invention and its operation, what I claim therein as new, and for which I desire letters patent, is extending the shaft of the presser down from the pressing arm to the bottom of the flyer, and providing the lower end thereof with an arm, which, in combination with the spring attached to the flyer, enables the attendant to throw back the presser, which is there retained till the spool is doffed and replaced by an empty one, as herein described.

E. B. BIGELOW.

No. 3927.

What I claim as my invention, is the combination of the grooved block which embraces the saw with the bar joined thereto in the middle, and the file-frame which slides vertically and horizontally on the bar; the said file-frame being provided with a spring to bear the file on the saw, as described in the foregoing specifications.

JACOB ARNDT.

No. 3928.

What I claim as my invention, and desire to secure by letters patent, is the mode of equalizing the tension of the cord or chain of the barrel, by the combination of the lever, link, and spring, whether constructed and arranged precisely in the manner described, or in any other mode substantially the same.

JOSEPH IVES.

No. 3929.

What I claim as my invention, and which I desire to secure by letters patent, is the mode or manner of casting pipe-boxes for carriage and other

wheels, by the use of the segment core, constructed and arranged and used in the way described, for chilling or hardening and finishing the interior surfaces of the boxes.

JOHN HUNTINGTON.

No. 3930.

Having thus fully described my improvement, what I claim therein as new, and desire to secure by letters patent, is the combination of the guide carriages or indicators on each side of the pulley, with the *screw and lever power-press*, to prevent the lateral motion, while it allows a free vertical action, all as above described.

P. G. GARDINER.

No. 3931.

What I claim as my invention, and desire to secure by letters patent, is the use of the small valves operating in the centre of the main valves, and by the same motions substantially as above described, by which arrangement much of the power required to open the valves in the old way is saved for the direct action of the engine.

SAMUEL TALBOTT.

No. 3932.

What I claim as my invention, and desire to secure by letters patent, is the combination of the inclined plane, rollers, and spring, in the manner above described, for any of the above mentioned, or for any other purpose to which the same may be applicable.

LEVI BISSELL.

No. 3933.

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the double acting suction and force pump, with one valve, constructed and operating substantially in the manner and for the purpose herein set forth.

JOSEPH H. WEBSTER.

No. 3934.

What I claim as new, and desire to secure by letters patent, is the combination of the spindle, the end of which is adapted to the reception of the strand for forming with the sliding block or guide, for winding on after the strand is formed, as described; also the combination of the spindle in the machine for laying the rope, the end of which is adapted for receiving the rope, while giving the after turn with the sliding block for winding on the rope after it is laid, as described.

This invention differs from Townsend & Durfee's reel, patented in 1830 or 1831, in the following particulars: In the use of that reel it was necessary, when a single length of the walk or building was spun in yarns, to lay the same into rope, and reel the same before spinning a second length.

In spinning a second length, the threads or yarns were united to the several threads or yarns already finished, by splicing or spinning into them, and so a second part of the rope was made and reeled as before.

By this process being repeated, the rope was made of the desired length, but could not be made *patent formed* without lacing or splicing in the strands of the threads or yarns.

This invention differs from the ordinary forming jacks in use, in the spindle to receive the portions of the strand when formed, and in the gearing to guide the strand when reeled upon the spindles. It also differs from the laying jacks in common use, in having spindles to carry the indefinite length of strand, which at the same time gives the fore-turn for laying, and a spindle to carry the indefinite length of rope as it is finished, at the same time giving the after-turn for laying.

The term *formed rope*, sometimes called *patent formed*, implies that the yarns or threads of the several strands receive their relative place and bearing in the strand by the following process: A certain number of threads or yarns are passed through the centre of a gauge-plate forming the centre of the strand, while all the other threads or yarns forming the entire strand are arranged in circles around the centre, each passing through the plate separately, and receiving its exact and similar place in the strand, which is retained by the strand so formed being passed through a close tube, and followed by twist from the forming jack. This is what is called forming rope, and by the machinery hitherto used ropes could not be formed to exceed the length of the building in which they were made. In making *laced rope* it was customary to form the strands the length of the walk, and, cutting them off, lay the part so formed into a rope. The part so finished was then reeled upon Townsend & Durfee's reel, and a new set of strands formed, which were joined to its corresponding strand on the reel by knotting the yarns two and two in each strand, and hauling them together by lacing a yarn through the bends of yarn.

This lacing occupied some six to eighteen inches, and the yarns, in twisting in this place, lost their bearings in the strand, as the outside yarns were drawn tight by winding round the centres, which became proportionably loose and made a weak spot.

The forming of full length strands could not have been done by any forming jack constructed on the principle involved in the reel of Townsend & Durfee hitherto patented, since, in the use of that reel, the rope or strand was passed through a hole or aperture in the forward bearing of the spindle, and could not have been reeled smoothly or without displacing the form of the strand. In the use of the new machinery, on the contrary, the most powerful stretch, both of the strand and rope, is maintained through every part of the process of the manufacture, which, adding greatly to the hardness and solidity of the rope, is altogether essential for railroad purposes.

The inventions in use in Europe by which twine and small cordage are made of great length in a square room, it is believed, would utterly fail when introduced for the manufacture of railroad rope, for reason of the immense power that is necessary in the manufacturing of a rope of such great length and size, often weighing twenty thousand pounds in a single length of hard and solid rope.

EDWARD S. TOWNSEND.

No. 3935.

What I claim as my invention, and which I desire to secure by letters patent, consists in the combination of the adjustable vibrating roller of inclined blades with the revolving cylinder of cutters, arranged and operated in the manner set forth.

GEORGE A. COFFMAN.

No. 3936.

Having thus fully described my invention, what I claim therein as new, and desire to secure by letters patent, is the combination of a shaft, having two or more series of cams thereon, with a common hemp break, such as is used by hand; said shaft having a lateral motion so as to bring either of said cams into action at will, the whole being constructed and arranged substantially as herein set forth.

P. G. GARDINER.

No. 3937.

Having thus fully described the manner in which I construct my improved machine for polishing flat plates or tables of marble, or other substances, I do hereby declare that I do not claim as new either of the individual parts of said machine, but limit my claim to the combination of said individual parts, as above made known; said parts consisting of the reciprocating polisher, combined with the crank wheels, with the driving wheel, and with the sliding head and regulating rods and levers, so as by said combination to constitute a machine substantially the same with that herein described.

JACOB ZEIGLER.

No. 3938.

Having thus fully described my machine for cutting and grinding corn and fodder, and other vegetable substances, and explained the operation of the same, what I claim as new therein, and desire to secure by letters patent, is the arrangement of the knives upon the wheel and the openings under the same, (for allowing the substances acted upon by the knives to pass through the same.) in connexion with the crushing or grinding surface of the opposite side of the said wheel, and the combination of the cutting and grinding wheel with the stationary wheel and the semicircle, as herein represented and described. The peculiarity of my machine consists in the cutting knives being placed upon one side of a wheel, and the grinding projections, or teeth, upon the other side of the same; the substances, as they are acted on by the knives, passing through the cutting and grinding wheel, (through the openings under the knives,) and being ground on the other side of the same, as herein described.

JACOB ROYER.

No. 3939.

Having thus fully described my improvement, what I claim therein as new, and desire to secure by letters patent, is the turning plate in combi-

nation with the grate of the fire chamber, for the purpose of conducting the ashes from the fire chamber above, under the grate.

JOHN T. DAVY.

No. 3940.

What I claim as my invention, and desire to secure by letters patent, is the fastening of the string to the shorter arm of an elbow-lever, or any other lever or levers the same in principle, the extremity of the longer arm of which being furnished with a perforation or slot through which a thumb or key-screw passes, the lower extremity of which passes again through a plate inserted in the tuning block, by which means the instrument may be tuned in a very simple, easy, and expeditious, but precise manner, by any professor or amateur of music, without the aid of any professional tuner; the whole of which improvement being constructed and operating substantially as herein above set forth.

LOUIS RUECKERT.

No. 3941.

The invention of this entire instrument I do not claim; but what I do claim as my invention, and desire to secure by letters patent, is the mode of adjusting and comprising the point for use, and releasing the same, when necessary, from the instrument; this is effected by constructing that part of the jaws extending from *c* 1, to *c* 2, in a tapering form; so that the jaw shall be at *c* 1 about two-thirds as thick as at *c* 2.

2d. By making the hole through the socket of the same degree of taper as the jaw, and of proper size to exactly embrace the jaw, when driven home to its place, as seen in figure 1.

3d. By making a channel on the one side of the jaws, next to the jaw, about one-tenth of an inch deep, about seven-eighths the length of the jaw, terminating the channel about one inch from the end.

4th. By making the point about one thirty-second part of an inch thicker than the depth of the channel in C C.

To adjust the point and secure it firmly in the instrument for use, I place the point in the channel made in C C, as seen in figure 3; then, holding the point in the channel, I slide the point and the jaw into the socket; then, holding the instrument by the handle, with the sharp end of the point upwards, I strike the end of the jaw upon some hard substance, as a small block of wood, which, by the force of the blow, causes the jaw to settle firmly into the socket, and produce a pressure against the point, which secures it firmly in its place. The instrument is then ready for use.

When I wish to release the point for sharpening, &c., I hold the instrument by the handle with the sharp end of the point upwards, and strike the end of the jaw upon the block of wood, which instantly displaces the jaw and releases the point.

JOHN C. DEXTER.

No. 3942.

I claim the above described manner in which I arrange the parts of my brick machine which form and compress the brick, and afterwards dis-

charge it from the mould ; that is to say, the arranging and operating them so that while one brick is being compressed in one compartment of the mould, by the compressing pistons, the discharge piston shall be performing its office of expelling from the mould the brick which had next previously been formed, the mould being progressively moved forward at regular intervals of time, so as to present that compartment of it in which the brick has been compressed to the action of the discharging piston, where the compressing pistons next enter the preceding apartment, to effect the formation of a brick therein.

JOHN WAIT.

No. 3943.

Having thus fully described the manner in which I construct my improved rotary hydraulic steam engine, and shown the operation thereof, what I claim therein as new, and desire to secure by letters patent, is the combination with each of the steam arms of a tube, one end of which shall dip into a reservoir like that marked *f*, which is to contain a portion of water or other fluid, which fluid, in its heated state, is to be carried into the steam tube by the centrifugal action of the engine, and is to enter said steam tube near the orifice for the emission of said steam; said water or other fluid being allowed to flow back into the reservoir, so that it may be continuously used for the purpose and in the manner herein set forth.

I do not claim the introducing of a jet of cold water into the revolving arms, for the purpose of condensing the steam, as was proposed in a rotary engine known as Saddler's, the water or other fluid used by me being, as heretofore stated, employed in its heated state, and for a purpose altogether different from that of condensation.

JAMES BLACK.

No. 3944.

Having thus fully described our machine, and its operation, what we claim therein as our invention, and desire to secure by letters patent, is the method, herein described, of tinning the inside of lead pipes in the course of manufacture, by passing the melted tin down into the mandrel and out at the side thereof, as above made known, whether applied to this machine or any other, substantially the same.

HENRY M. WARD,
SAMUEL L. SELDEN,
ELISHA Y. KNEELAND.

No. 3945.

Having thus set forth the nature and principles of my invention, that which I claim is as follows, viz:

I claim the spring bar or lever in combination with or as applied to the rest plate, and arranged and operating substantially as set forth, for the purpose of conveying or feeding the wire into the cutting dies, in the manner as described.

Also, the improvement by which the proper adjustment and holding of the rivet blank during the operation of forming the head thereon, and the

discharging of the rivet from the apparatus after its formation is effected; the said improvement consisting in arranging *within* the *movable* cutter the forcing mechanism, or movable piston, &c., connected with it: the whole operating and being arranged substantially as set forth.

HORATIO G. REED.

No. 3946.

Having thus fully described my improvements, what I claim as new, and desire to secure by letters patent, is the combination of a pipe or tube, constructed and arranged substantially in the manner set forth, with a stove or fire-chamber, as above described, for ventilating the room and supplying air at high temperature.

I also claim, in combination with the above, the radiator or column, the outer case surrounding the stove, and the eduction or hot air pipes; constructed and arranged in the manner and for the purposes herein specified.

JOHN MORRISON.

No. 3947.

Having thus fully described the nature of my improvement, and shown the manner of carrying the same into operation, what I desire to secure by letters patent is the use of the continuous strip of wood, or other elastic substance, combined with the under rails, as described herein, and the wrought or cast-iron top rails of the plate or bridge, or any other form, substantially in the manner set forth.

I also claim the manner of connecting and holding together the upper and under rails of iron, as herein described, so as to make the under rail serve as a *chair throughout its whole length*, to the top rail, the latter being imbedded in a channel in the former; or, as in the other described plan, when the top rail is grooved on the under side, and rests on the under rail as a saddle, thereby giving strength and stability to the joints of both the upper and under rails.

I claim the use of cast-iron top rails, when in connexion with iron under rails.

JOHN ELGAR.

No. 3948.

What I claim as my invention, and desire to secure by letters patent, is the combination of the weight and catch with the bobbin or spool, constructed and arranged in the manner and for the purpose substantially herein set forth, so that when the weight is drawn up it will relieve the catch, and allow the spool to unwind and the weight to fall.

E. B. BIGELOW.

No. 3949.

I do not claim to have invented an auger-bit or a handle, nor do I claim any of the parts employed herein, taken separately from the uses to which I have herein applied them; but I do claim as new and of my own invention, and desire to secure by letters patent, the application of the tapered tang, with two counter-sunk sides, forming diagonal lips, to overlie two

edges of a corresponding mortise in the centre cylinder, in combination with the sliding collar, driven on by either half handle, when screwed up, so as to place and hold the lips of the tang over the edges of the mortise, and thereby hold the auger-bit secure in the handle, at the same time facilitating the separation and exchange of the parts; the whole constructed and operating substantially as herein described.

D. C. STONE.

No. 3950.

What I claim as my invention, and desire to secure by letters patent, is constructing the cylinder of cutters with parallel bars and spirally arranged cutters, made adjustable with screws and nuts, in the manner and for the purpose described.

I also claim the arrangement of the smoother in combination with the rotating cutters.

I likewise claim the manner of adjusting the vice-nut, for throwing the carriage in and out of gear with the screw, by means of the slide and screw.

JAMES D. WILLOUGHBY.

No. 3951.

Having thus fully described the nature of my improvement in the machine for hulling cotton seed, I do hereby declare that I do not claim the double beater, or the rack, as being new in themselves; but what I do claim as new, and desire to secure by letters patent, is the combining of such a beater and rack with the cylinder, concave, and riddle, constituting the main operating parts of the above named machine for hulling cotton seed, by which combination said machine is essentially improved, and economy greatly saved.

JABEZ SMITH.

No. 3952.

What I claim in the above described instrument, and desire to secure by letters patent, is the combination of the spring with the oil can or syringe, substantially in the manner and for the purpose above described.

ELIPHALET S. SCRIPTURE.

No. 3953.

What I claim as my invention, and desire to secure by letters patent, is hanging the spindle, on which the horse-wheel turns, to journals or trunnions, to admit of canting the wheel for admitting the horses, &c., within the rim, as herein described, or in any other substantially similar.

I also claim applying the circular metallic rim as a propelling power, in combination with the two rollers, placed in axles, which are connected by two cogged wheels geared into each other, thus combining the adhesion which is required on both sides of the rim, as described.

JOHN HAW.

No. 3954.

I claim the arrangements of parts constituting the peculiar take-up motion, in combination with the machinery for arresting the progress of the loom when a filling thread breaks, as the same is represented in the drawings, and as above described, and as combined and operating substantially as set forth; I also claim the mode of operating the revolving shuttle box, (represented in the drawings,) or turning the same round at suitable intervals of time, for the purposes set forth, namely, by means of the vertical cogged wheel having pins extending from its sides in combination with the dogs of the notched circular plates, and with the pinion on the revolving shuttle box; the same being arranged and operated substantially as set forth.

I also claim the employment and use of circular notched plates in combination with the connected pawls or dogs, as above described, whether the same actuates the shuttle box by the mechanism which intervenes between the said plates, with their appendages and the said shuttle box, as herein before set forth, or by any other which may be adapted thereto; the whole being arranged and operating substantially as above specified.

JAMES NIELD.

No. 3955.

I claim the peculiar "take up motion," and machinery for arresting the progress of the loom when a filling thread breaks, as represented in the drawings; the same consisting of a series of looped strings or other similar contrivances fixed to the breast beam, and arranged in other respects as set forth, the moving or hinged frame, and other mechanism, intervening between the said frame and the usual hand lever and shaft of the ratchet wheel, or connecting the same together; that is to say, I claim the combination of the said mechanism for the object and purposes specified, the same being substantially as set forth.

JAMES NIELD.

No. 3956.

What I claim as my invention, and desire to secure by letters patent, is the method of making said paint by the composition of the substances mentioned, in the manner above mentioned; the same to be made of different degress of thickness, so as to be used either as a paint or a putty.

THOS. G. WARREN.

No. 3957.

We do not claim a wheel having a series of dicing tools alone applied to it, as heretofore made, or one having a series of polishing tools alone; but that which we do claim is the arranging of a series of dicers, and one of polishers, upon wheels, so as to be operated with respect to each other substantially as described; and furthermore, we do not claim the use of a tool for cutting or repairing the dicing tools; but that which we do claim, is the arranging and applying such a tool (or the tool in) upon the top of the curved table, in such manner as to admit of its being readily forced

forward against the dicers, at any time whenever necessary for the purpose of cutting them, as herein described.

RUFUS BRACKETT,
HENRY BRACKETT.

No. 3958.

I do not mean or intend to claim as my improvements or invention any of the parts of the machine or machines, presses, or letter copying machine, herein delineated or described, nor do I intend or mean to limit myself to the employment of any particular material or meterials in the construction thereof, but to use any which are fit and proper for the purpose intended. But I do hereby *claim* the use and application of a flexible or elastic platen in the manner herein described, the application of pressure thereto in printing presses, copying presses, lithographic presses, and zincographic presses, by means of a liquid aeriform fluid, in the manner also herein described, and the arrangement of the machinery or parts of the said presses, as herein described, for the purpose of applying such pressure of a liquid or aeriform fluid to such flexible or elastic platen.

JOS. SAXTON.

No. 3959.

What I claim as my invention, and desire to secure by letters patent, is the construction of the buckets above described, either longer or smaller than herein described, but not varying their relative size.

OBADIAH AYLSWORTH.

No. 3960.

What I claim is the employment of the apparatus termed the working column in combination with the uplifting valve and float, as herein described, whereby the pressure of steam on the working column is added to the pressure on the safety or uplifting valve, for the purpose of opening it when the water descends below a given point, and which, at the proper height of water, permits free action of the uplifting valve, as herein described; and I also claim the employment of a pendulum so situated, or so suspended, that by the rocking, tilting, or creening of the boiler or boat upon which such pendulum shall be employed, the said pendulum shall so attach itself to, or so suspend itself upon a tackle, lever, or pivot, as thereby to apply its weight as a moving power to the opening of a safety valve or valves for steam boilers, as herein described.

ABRAM PATERSON.

No. 3961.

Having thus fully described the nature of my planing machine, and shown the construction and operation of the respective parts thereof, what I claim therein as new, and desire to secure by letters patent, is the particular manner in which I form and arrange the parts concerned in fastening the cutters or irons in the planing wheel, under that form or modification of it which is last described in the foregoing specification; these parts con-

sisting of a strip of metal inserted in the arms, and of the screws, with their tapering points, arranged and operating as set forth, and also the analogous arrangement of the screws and wedge pieces for fastening the cutters of the tonguing, grooving, and jointing heads; the respective irons or cutters of these heads being formed, arranged, and combined in the manner above described.

BENJ. BICKNELL.

No. 3962.

What I claim as new, and desire to secure by letters patent, is—

1st. The above described cross beam, combined with the pedestals, the springs, the connecting bars, and the housings, substantially as described, by which a yielding capacity is given to the superstructure or frame part of the truck, without affecting the condition of the remaining wheels.

2d. The formation of the journal boxes, as described at figures 2 and 3, by which the axles of the truck may vibrate laterally, (the one independent of the other,) to accommodate their position upon the track, (and so making curves easy,) which, combined with the other yielding qualities of the truck, acting together, produce a semi-universal joint effect.

FOWLER M. RAY.

No. 3963.

What we claim as our invention, and desire to secure by letters patent, is the arranging of the upper and lower turning sashes of a window in *sliding frames*, substantially in the manner hereinbefore described, so that they may be turned on their centres, or axes, for the purposes stated, the space at the top of the boxing being formed to allow the frames, &c., to be pushed up, as hereinabove described, in order to effect the above-named turning of the sashes; the whole arrangement and operation being substantially as hereinbefore set forth.

C. J. SCHIRER,
THAD'S W. CROSS.

No. 3964.

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the horizontal sliding forked stuffer and tube, and clamp, with the hopper, constructed and arranged in the manner and for the purpose set forth, or other mode substantially the same, by which analogous results are produced.

THOS. WILES.

No. 3965.

What we claim as our invention, and desire to secure by letters patent, is the combination of the materials, in the general proportions above described, for making an adhesive plaster.

We also claim making plasters *porous*, or *pervious* to fluids, by perforating them with numerous minute holes.

WILLIAM H. SHECUT,
HORACE H. DAY.

No. 3966.

Having thus fully described the nature of my improvement in the drip-cup of the the solar lamp, what I claim as new therein, and desire to secure by letters patent, is the combining with the draught holes of such a cup a rotating or other valve or air regulator, which is capable of being nearly, but not entirely closed—such as is herein described, and substantially in the manner and for the purpose above set forth.

I do not claim such a valve, or regulator of the draught, as new in itself, but limit my claim to the combination thereof with a drip cup of a solar lamp.

E. WHELAN.

No. 3967.

What I claim as my invention, and desire to secure by letters patent, is the application of an oval wheel, flat or convex, to operate as described in the foregoing specification.

I do not claim any part of the machinery used in the construction thereof.

GERRETT ERKSON.

No. 3968.

Having thus fully described the nature of my improvements in the manner of arranging and combining the apparatus concerned in the arresting of the momentum, and in the throwing of the shuttle, what I claim therein as new, and desire to secure by letters patent, is the employment of the spring on the inside of the projecting guard, in the manner and for the purpose described. I also claim the particular manner of combining the treadles, the wag staves, and the picker staves, with each other, as herein described and represented, so that they shall co-operate in producing the required motion, as set forth.

I do not claim as new the manner of forming the picker staves, with a rocker on their lower ends; nor do I claim the using them without the ordinary picker, this having been previously done, but limit my claim to the arrangement and combination above named.

DANIEL BARNUM.

No. 3969.

What I claim as my invention, and desire to secure by letters patent, is the application of air, through metallic pipes or tubes, to mill-stones, as herein described, to prevent millstones from heating, and also facilitate grinding.

FERRIS FRELIGH.

No. 3970.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I construct the tongue of my buckle, substantially as herein described, the tongue being combined with a spring, and so operated on the same that it enters the holes in the straps in the direction and manner substantially as set forth.

KASSON FRAZER.

No. 3971.

What I claim as my invention, and which I desire to secure by letters patent, is the mode herein described of warming the bees in the hive—the hot-air tube, in the lower part of the hive, arranged with reference to the entrance as described; its upper part provided with a drum, surrounded with wire gauze; the whole arrangements of parts of the said heating apparatus, and purpose of the same, being as herein described.

SILAS HART.

No. 3972.

What I claim as original is the combination of the moth trap or harbor, before described, with the suspended hive, constructed and arranged in the manner set forth.

A. SANBURN.

No. 3973.

What I claim as my invention, and desire to secure by letters patent, is the construction and arrangement of the bars for the purpose of saving all the gravy, as herein set forth, whether constructed in the precise manner above described, or in other mode substantially the same, by which analogous results are produced.

JOSEPH HAWKINS.

No. 3974.

What I claim as my invention, and desire to secure by letters patent, is, constructing boats of sheet metal, pressed into form in moulds, with beds, flanches, and mouldings, as herein described, for the purpose of taking up the surplus metal in forming the boat, to prevent wrinkles in the sides thereof, and for stiffening it, as above set forth.

I further claim the recess, moulding, and flanch, to receive the gunwale, which takes up the surplus metal along the upper edge of the boat, and gives sufficient strength and stiffness without frames or timbers inside; constructed substantially in the manner and for the purposes above specified.

JOSEPH FRANCIS.

No. 3975.

Having thus fully described my improvements and their design, what I claim as my invention, and desire to secure by letters patent, is constructing the stove in the manner described, with the sides and end plates splayed out at the joints or the corners in combination with the corrugated sides, substantially in the manner and for the purpose above specified.

ANSON ATWOOD.

No. 3976.

Having thus fully described the nature of my improvements in the cooking-stove, and shown the structure and operation of the respective parts

thereof, what I claim therein as new, and desire to secure by letters patent, is, first, the manner of combining the jamb flues with the upper part of the boiler space, and with the closed ash-pit, for the purpose of feeding the fire, and of carrying off the effluvia from said boiler space.

I also claim the combining with the foregoing the descending flue, furnished with a valve, the said flue space and its valve serving also to carry off the effluvia, and to regulate the draught down the jamb flues, said flues being arranged and connected with the other parts of the stove, as set forth.

GOULD THORP.

No. 3977.

What I claim as my invention, and desire to secure by letters patent, is the mode of arranging rollers 1, 2, and 3, for the purpose of regulating the delivery of the yarn, the arrangement being such, by placing one of the rollers between and above the other two, and carrying the yarn under roller No. 3, then over No. 2, and then under No. 1, and from thence to the heddles, so that the tension of the yarn draws the upper one upon the other two, to increase the bite on the yarn, and thus prevent slipping, all as herein described.

BENJAMIN SLINGERLAND.

No. 3978.

What I claim as my invention, and which I desire to secure by letters patent, is the before described mode of scraping the bottoms of rivers by operating a floating scoop by power machinery placed in a separate vessel, anchored on the opposite side of the river, said floating scoop being attached to an anchor up stream, so that the current will carry back the scoop to the opposite side of the river at the termination of every operation of the said scoop, for a repetition of the action of the scoop, the vessel containing the engine being moved up or down stream, as the work progresses, by the power of the engine, as described.

HENRY McCARTY.

No. 3979.

Having thus fully described my improvement, I wish it to be understood that I do not claim constructing wheels with the spokes standing bracing, by projecting inner ends out from the plane of the wheel on each side, nor do I claim screwing the ends up firmly against a centre, permanent projection on the hub, as that would not effect the object I have in view, which is to continually tighten the spokes and brace them out against the felloes as they wear loose; and what I do claim as my invention, which I desire to secure by letters patent, is the combination of the pipe-box with the cheek pieces, into which the spokes are inserted, and fastened by two plates on their outside—a space between said cheeks being left, so that they can be forced towards each other to tighten the spokes as they wear loose or shrink, and by that means firmly brace the wheel, which can be readily taken to pieces, and any broken or defective parts replaced by perfect ones.

ELIPHALET S. SCRIPTURE.

No. 3980.

What I claim as my invention, and desire to secure by letters patent, is the combination of the die with the rotating stock for the purpose and in the manner described. I also claim composing the die of the flat face, the groove, and the cutter, as described, so as to perform with the same instrument the three operations of hammering, rounding, and cutting.

NATHAN BRAND.

No. 3981.

I claim the making the boxes to slide vertically in the connecting-rod in combination with extending or lengthening the crank pins of the wheels beyond the said boxes, so as to slide through them in the direction of their axes, as set forth—the whole being for the purpose of converting all of several wheels of the engine into drivers.

HOLMES HINKLEY.

No. 3982.

Having thus fully described the manner in which I construct my double-acting turpentine shave, and pointed out the operation thereof, what I claim therein as new, and desire to secure by letters patent, is the connecting of the two gouge-formed shaves or cutters with their levers, by means of the double springs, in combination with the concave guide band; by which combination the shaves or cutters are moved in a curve the reverse of that described by the ends of the levers from which they derive their motion; and I do hereby declare that I do not intend by this claim to limit myself to the precise form in which the instrument is herein represented and described, but to vary the same as I may find expedient, whilst I attain the same end by means substantially the same.

G. R. TALLY.

No. 3983.

I do not claim setting the head and tail block by means of a rack pawl and level; but what I do claim is the before described combination of the railway and wheel with the sliding bar, hand, and lever, arranged and operated in the manner and for the purpose above set forth.

I also claim the setting of the reversible cogged bar, by means of which it can be adjusted to the hand when reversed or shifted for cutting different thicknesses of boards in the same log, and thus avoid the necessity of spoiling the first board cut after shifting or turning the cogged bar described.

BENJAMIN WEBB.

No. 3984.

I do not claim to be the inventor of hollow skeins for axletrees, for these have been heretofore used and secured permanently to the axletrees; but what I do claim as my invention, and which I desire to secure by letters patent, is the before described manner of fastening the skeins to the axletree, so that they can be tightened and turned, and changed in position,

whenever they become loose or uneven from the shrinking of the wood and the rubbing of the metallic surfaces, or from any other cause, by means of the aforesaid construction of the axletree and skeins, and arrangement of the screw-rods and nuts, used and operated in the manner set forth.

JAMES JONES.

No. 3985.

Having thus fully described the manner in which I construct my improved printing press, and shown the operation of the respective parts thereof, what I claim therein as new, and desire to secure by letters patent, is, first, the manner in which I have constructed, combined, and arranged the friskets, and the parts by which they are made to traverse through the machine, as set forth.

I do not claim the using of four friskets as in itself new, but I claim the manner and combination in which I use them, which are essentially different from any heretofore adopted; and these I claim, whether the form or forms of type be placed vertically or horizontally, and whether two impressions or one only be taken at the same time.

I also claim the manner of combining and arranging the parts by which the power is applied to the platens, through the intermedium of the revolving shaft, which is made to operate intermittingly, and to carry arms that bear upon the backs of the platens, as herein set forth.

JOEL G. NORTHRUP.

No. 3986.

And I declare my invention, under the present letters patent, to consist in the application to the lower end of the wooden pile, or a metal pin or shaft, of a broad metal screw or worm, for the purpose of enabling such a pile or pin to be inserted into or extracted from the ground, by causing it to turn upon its axis by means of cross levers, when it is placed with its point directed upon penetrable ground; and I claim, under the privileges of before mentioned letters patent, piles, pins, or shafts, so armed with broad metal worms or screws, whether the same be employed for piling ground for the support of buildings or embankments, or to obtain a secure hold of the ground for the purposes of mooring or holding fast ships and other floating or stationary bodies.

ALEXANDER MITCHELL.

No. 3987.

What I claim as my invention, and desire to secure by letters patent, is—

1st. The combination of the tension or yarn roller with the letting off motion, so that when the yarn roller is drawn forward by the process of weaving, the let off is put in motion, which relieves the yarn roller and allows it to fall back, and thus stop the let-off; and I also claim, in combination with the above, the break for preventing the yarn roller from moving while beating up the cloth.

2d. In combination with the measuring rollers, I claim the under wheel (2) and hand for measuring the cloth, as described.

3d. I claim the combination of the shuttle-boxes with the weight or

spring, by means of the chain and pulleys, and pin-wheel, with which the weight is made to connect, to change the pattern, while the machinery is guarded against injury if the shuttle should not be sent home.

4th. I claim, in combination with the pickers, the spring lever, arranged and operated as above described, so as to arrest the shuttle as it enters the box, and then to fall back to clear the point of the shuttle before the box changes.

Lastly, I claim the combination of the apparatus for stopping the loom; that is to say, the combination of the fingered lever with the levers (2,) and in the manner described, and, in combination with the above, the protector and stop on the wheel (2,) to arrest the motion of the crank shaft and throw off the shipper.

E. B. BIGELOW.

No. 3988.

I am aware that bevel wheels have been made dishing or concave, for the purpose of permitting other wheels to turn within their peripheries; and I am aware that a combination of wheels has been made in which the shaft of the last wheel passes through the shaft of the main or master wheel, and therefore I do not claim these as of my invention; but what I do claim, and desire to secure by letters patent, is the arrangement of the bevel cog wheels, with the shaft of the last wheel passing through the shaft of the main wheel in combination with the dished form of the main or master wheel, by which arrangement, in combining, the whole is rendered more compact than by any other with which I am acquainted; all as herein described.

RICHARD MONTGOMERY.

No. 3989.

What I claim as my invention, and desire to secure by letters patent, is running the self balanced gate on rollers, or pins attached to the posts and between the rails of the gate, by means of which the counterpoise employed in railway draw-bridges, as also a rail below or above in the passage of the gate, as in sliding-doors, are dispensed with, whether this be applied with the rails of the gate horizontal or inclined, to cause the weight of the gate to close it, as described.

ARNON BAKER.

No. 3990.

Having, therefore, described my improvement, I shall claim the revolving block and bit plate, as applied to each other and to the bolt, and operating upon the bolt through a spring lever or other suitable contrivance connected to the bolt, the whole being substantially as herein set forth.

JOHN OXNARD.

No. 3991.

I claim, first, employing instruments attached to a straight plate, and moving over a space equal to their distance apart, so as only to be in action a

small portion of time before they are relieved, substantially as herein set forth, the cutters each projecting over the one below it the depth of the cut to be made, as above fully made known.

Secondly, the method of moving the cutters from the stone, after every cut, as herein described, by means of the revolving of the vertical shafts, or any other means substantially the same, for the purposes herein described.

DANIEL PFISTER.

No. 3992.

Having thus fully described the nature of my improvements in the portable vapor bath, and shown the manner of using and the operation of the same, what I claim as new therein, and desire to secure by letters patent, is the combining of the hollow piston with the reservoir, which piston is made to regulate the elasticity of the vapor, in the manner and for the purposes herein set forth; said hollow piston also constituting a receptacle for such articles as it may be desired to convert into vapor by the heating of the fluid in the reservoir.

I also claim the particular manner in which I arrange and combine the respective parts of the burner or burners of my lamp; said parts consisting principally of the wire loop for sustaining the wick in a position nearly horizontal, and the sliding cover for regulating the flame—the whole operating substantially as set forth.

T. S. LAMBERT.

No. 3993.

What I claim as my invention, and desire to secure by letters patent, is the preparation of the hides or skins to be tanned, by puncturing or perforating them, either on the flesh or grain side, with holes extending either entirely or partly through, so as to admit the tannin more freely, and perfectly to penetrate and operate upon the skin or hide.

SIMON SNYDER.

No. 3994.

Having thus fully described the manner in which I consruct and arrange my apparatus for drying bagasse, what I claim therein as new, and desire to secure by letters patent, is combining with a steam engine, or other furnace used in manufacturing sugar, a horizontal range of triple flues, in such manner as that an endless apron or bagasse carrier may be made to traverse through two of said flues, whilst the heated air and gaseous products of combustion are made to pass through the third or middle flue, on its way to the chimney; the respective parts being arranged and operating substantially in the manner and for the purpose herein fully set forth.

GEORGE MERRICK.

No. 3995.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is the combination of the lamp, or other light, and tubes, substantially in the manner and for the purposes above described.

I also claim the telescope herein made known, having glass at its lower end and a mirror therein, and side pipes attached thereto, the whole being combined and arranged as herein before made known.

SARAH P. MATHER.

No. 3996.

What I claim as my invention, and desire to secure by letters patent, is the combination of the boiler with the steam and hot-air pipes, and having the communications between them regulated by valve, the whole being constructed and operating as above described.

I do not, however, intend to be understood as confining myself to the use of any particular metal in the construction of my said apparatus, nor to the precise dimensions of the several parts thereof, as above mentioned. These may be changed, according as circumstances may require.

JOEL H. ROSS.

No. 3997.

Having thus fully described my improvement in presses, what I claim therein as new is the combination of the series of toggle joints with the beam, in the manner described, so that they can have a lateral motion without straining the beam.

J. SLOCUM.

No. 3998.

Having, therefore, explained my improved pistol, I shall claim extending the rear end of the dog, or catch, rearwards, and beyond, when it is jointed to the tumbler of the percussion hammer, and connecting the upper end of the main spring to the dog, so as to cause it to operate upon the hammer, dog, and trigger, substantially as described, the same being for the purpose herein before specified.

Also, the combination of the fixed angular stud with the dog or catch, jointed to the tumbler, for the purpose of enabling a person to cock the percussion hammer, in the manner as above set forth.

Also, my new and peculiar arrangement of the pitman upon the seer of the trigger, (so as to operate as above described,) in combination with the construction and arrangement of the teeth upon the breech or rear end of the cylinder or series of barrels, by which improvement in constructing and arranging the aforesaid parts I am enabled to very much simplify them, in comparison with the manner in which they have heretofore been made and disposed.

ETHAN ALLEN.

No. 3999.

What I claim for my invention, and desire to secure by letters patent, is the substitution of red sandstone and clay, reduced to a powder in the natural state, or argil, silex, and the oxide of iron, for the stone or sessyl, or val de travers, or other assimilated materials, in combination with the mineral tar or sessyl, or with any other bitumens used in the formation of mastics, or in the use of red sandstone alone with the mineral tar, or other bitumens.

WILLIAM H. CHASE.

No. 4000.

Having thus fully described my improvement, what I claim as my invention, and desire to secure by letters patent, is the combining the catch bolt and bolt of the lock, so that one will slide within a groove in the other, in the manner and for the purpose herein set forth.

RHODOLPHUS KINGSLEY.

No. 4001.

What I claim, and desire to secure by letters patent, is the construction and use of wheels with two spokes in one mortise, in the manner and for the purpose above described.

G. L. ACKERMAN.

No. 4002.

What I claim as my invention in this machine, and desire to secure by letters patent, is the manner of using the dashers, or piston that is attached to the stem of the steam valve, in combination with, and working within, a short cylindrical vessel, or check chamber, which is open at top to allow a free passage to the steam in and out, and is furnished with an adjusting slide to regulate the escape of the steam; by which means the valve is made to take its seat without striking or noise.

JOHN COCHRANE.

No. 4003.

Having thus fully described the nature of my improvements in the auxiliary engine, what I claim therein as new, and desire to secure by letters patent, is, first, the manner herein described of completing the stroke, or traversing motion of the valve, by the commencing return stroke of the piston operating on the spring arms, substantially in the manner and for the purpose herein set forth.

I likewise claim the manner of regulating the stroke of the water-pump, by adjusting the same by means of a valve or cock, as set forth, so that a smaller and regulated quantity of steam shall be admitted to the lifting than is admitted to the forcing side of the piston, as described.

JOHN COCHRANE.

No. 4004.

I do not claim the combining with the posts, braces, and strings of a truss a series of supplementary braces, &c.; but what I do claim is the arrangement of such a series of braces upon the *outer sides of the truss*, and so that they shall extend above and below the cords thereof, and be confined to the truss, substantially as above set forth.

GEORGE W. THAYER.

No. 4005.

I claim as my invention the method of rendering India rubber fabrics solid and substantial, for the uses and purposes mentioned, by impregnating

and combining the gum with grit, iron or other metal filings, or other hard substances, in the manner specified; and therefore I solicit letters patent.

NELSON GOODYEAR.

No. 4006.

Having thus fully described my application of the self-adjusting platen, and shown its operation, what I claim therein as new, and desire to secure by letters patent, is the application of the hydraulic cylinder to the platen, of toggle-joint, and other progress in power-presses—whether it be by applying the cylinder direct to the platen, or through the medium of screws or wedges, racks and pinions, or other analogous devices, so that, through the medium of the spring and gearing attached to the press, an increasing weight is thrown upon the valve so as to produce the desired effect upon the platen; the whole being combined and operating in the manner herein set forth.

JOSEPH C. COLT.

No. 4007.

Having thus fully described our process, we wish it to be understood that we do not claim extracting the tannin from the coloring-matter in quercitron bark, as that has before been done by the introduction of gelatine, by which it is separated; but what we do claim as our invention, and desire to secure by letters patent, is the process of separating the yellow coloring-matter and tannin, or astringent matter of quercitron bark, substantially as herein described; that is to say, by partially evaporating the decoction, and then allowing the coloring-matter to settle, and then drawing off the astringent liquid and preparing it for the uses intended.

GEO. W. CLOSE.
EDW'D FIELD.

No. 4008.

I do not claim the particular form or description of apparatus, still, or retorts, as set forth in the drawings (Nos. 1 and 2) herewith. What I claim, is the progress or mode of producing the American oil, as set forth in the above specification and drawings.

Such apparatus may be modified or varied, as circumstances may require from time to time, when deemed expedient.

What I claim is the process, as herein above set forth, of producing the substance which I denominate the American oil; such process being conducted substantially in the manner described.

W. T. CLOUGH.

No. 4009.

Having thus concluded my description, I shall claim the employment and use of the longitudinal centre rail-pieces and traverse rest-bars, as combined with or applied to the rectangular carriage, and for the purposes as above described.

JAMES DANE.

No. 4010.

Having thus described my invention, I shall claim a feeder constructed, substantially as described, of one or more troughs or apartments, and with discharging orifices and adjustable valves adapted to them; the whole being for the purpose as herein set forth.

ALEXANDER BOYD.

No. 4011.

Having thus fully described the nature of my improvements, and shown the manner in which I have combined them with the lock for safes, vaults, &c., invented by William Hall, and which may also be combined with locks of other constructions, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have combined the revolving scutcheon, the steel plate, and the cam, with each other, and with the tumbler; under which arrangement the tumbler is left free to rise by the action of the revolving scutcheon, and is raised by a pin or projecting piece on the bit of the key; the whole combination and arrangement being substantially the same with those herein set forth.

I also claim the combining of the pipe or tube with a revolving scutcheon, in such manner as, by means of a slot in said tube, to admit a key having the ordinary bit or bits, that are to act upon the tumblers and bolt, as usual, and under the arrangement herein made known.

H. G. JONES.

No. 4012.

What I claim as constituting my invention in the above-described process, and desire to secure by letters patent, is the preparing of designs in relief, in copper or other suitable metal, for the purpose of printing typographically, or for other purposes, to which such designs are applicable, in the manner herein set forth of effecting the same; that is to say, by coating a block or plate of any suitable substance with a ground through which the lines of such design may be cut or traced as set forth, and giving the same a coating of conducting substance, so that a plate in relief may be obtained therefrom by the electrotype process, as described.

A. W. THOMPSON.

No. 4013.

We shall therefore claim the combination with the series of cutters, of the passages, &c., leading from the cutters and passages; the whole being for the purpose of making match-splints from a block or blocks, as described. Also the combination with the aforesaid cutters and passages of one or more dipping-frames, arranged and operating, with respect to them, substantially as herein before described. Also our improved manner of making the dipping-frames, viz: in sections of separate pieces or plates, as described. Also the combination of mechanism, by which each of the blocks of wood is held down upon the carriage and progressively forced forward against the board; the said mechanism being applied to the carriage and board, and constructed and operating together, substantially as hereinbefore set forth.

Also the combination of machinery, by which the dipping-frames are progressively moved forward; the said machinery being connected with and intervening between the carriage and the said dipping-frames, and operating substantially in the manner as hereinbefore explained.

ASA FESSENDEN,
LUKE L. KNIGHT.

No. 4014.

Having thus fully described my machine and its operation, what I claim as my invention, and desire to secure by letters patent, is the apparatus for skimming a liquid, by means of a vessel in which the scum is collected by the revolution of the flanch or sweep, forming a kind of spoon, acting down below, but very near the level of the scum, as set forth.

C. HARIVEL.

No. 4015.

What I claim as my invention, and desire to secure by letters patent, is—

Firstly. The manner of combining the heddles and lay, substantially as herein described, by means of the vibrating frame and lifters, *b* or *a*, and endless series of plates, constructed and arranged as herein set forth, instead of the usual way, by means of cams, treadles, &c.; thus simplifying the operation, and consequently producing a saving of expenses.

Secondly. Constructing the double hooks on the lifters, in the manner described, by gradually increasing the distance between the upper and lower hooks of each one of the series of lifters from back to front, so that the back harness shall be raised higher than the front one in proportion to its distance from the cloth.

WM. TOWNSHEND.

No. 4016.

Having thus fully described the nature of my improvement in building vessels, and shown the manner in which the same is carried into operation, what I claim therein as new, and desire to secure by letters patent, is the manner of attaching a movable to a stationary keel, and of shipping and unshipping the same by means of bolts and chains, substantially as herein set forth.

THOMAS F. GRIFFITH.

No. 4017.

Having thus fully described my improved planing machine, what I claim therein as new, and desire to secure by letters patent, is—

1st. The combination of the veneer saw with the planing wheel, for the purpose of reducing the plank or board to a uniform thickness; and,

2d. I also claim the combination of the veneer saw for reducing the plank or board to a uniform thickness with the tonguing and grooving wheels, as herein described.

3d. I also claim the manner of forming the tongue by the two tonguing-wheels, having pointed cutter irons with two cutting edges; the one cutting

the side of the tongue, the other the shoulder of the same: the shafts of the said wheels standing at an angle of forty-five degrees, more or less, and crossing each other at or about right-angles.

4th. I also claim, in combination with the tonguing-wheels, the separate wheel for rounding the tongue.

5th. I also claim the use of one of the tonguing-wheels (the other being removed) for cutting a rebate upon the edge of the plank, where they are intended for overlapping each other, as in weather-boarding.

6th. I also claim, in combination with the planing, tonguing, and grooving-wheels, the wheel for forming a bead upon the edge of the board.

7th. I also claim the stationary knives for cutting off the stub-shot from the end of the plank, in combination with the feed-rollers.

RIED R. THROCKMORTON.

No. 4018.

What I claim as my invention, and desire to secure by letters patent, is the connexion of the roost, whether of chickens or other fowls, with the bee-hive or palace; the use of the roost as a lever or instrument by which the passage or passages of the bees (into and out of the hives) are shut at night and opened in the morning, or any other manner of using the roost of fowls, whether the roost is a pole, a rope, or any other thing.

GEORGE UPHAM.

No. 4019.

Having thus set forth our invention, we shall claim one or more supplementary strings, damper, and bridge, (or other analogous contrivance for supporting the strings, and checking their vibration, as above set forth,) in combination with the string or strings, and hammer beneath the same, the supplementary string being arranged, tuned, and operating, with respect to the strings of a note, and struck by the same hammer substantially in the manner above specified. We also claim the making the pad of the hammer-head of different degrees of elasticity, or harder in the part of it directly beneath, and which acts upon the supplementary string, than it is in the part or parts beneath, and which strike the other strings, the same being for the purpose above explained.

CHARLES F. OLIVER,
GEORGE W. JACKSON.

No. 4020.

Having thus described my invention, I shall claim my improvement in dredging machinery; the same consisting in the arrangement of the mast directly upon, and so as to be supported by, the movable crane, in such manner as to be moved by and with the crane whenever the latter is turned horizontally towards the right or left, instead of making the [mast] said a fixture to the deck of the vessel or dredge, as heretofore.

I claim the above described peculiar arrangement, with respect to each other, of the capstan and crane, and, in combination therewith, that of the chain which elevates the excavating bucket, the latter differing from other arrangements thereof in being carried through the rear or after end of the crane, in the manner and for the purpose as herein before specified.

OLIVER ALLEN.

No. 4021.

Having thus fully described my manner of forming hat bodies, what I claim as my invention, and desire to secure by letters patent, is the manner of constructing hat bodies entire—brim, body, and crown—of two pieces of cloth or other material, cut out in the form and united in the manner herein described and represented, for the purpose of making a stronger hat than is made in the usual manner of forming the crown, brim, and body of a hat of separate pieces, and likewise for economising labor and material.

ISAAC L. CHAPMAN.

No. 4022.

Having thus fully described the construction and operation of our improved combined scutching and hackling machine for hemp or flax, what we claim as new therein, and desire to secure by letters patent, is the form and arrangement of the rest and the standards, as herein described and set forth. We also claim the rack, in combination with the improved combined scutcher and hackle, for separating the tow from the shives and dirt, as herein described. We also claim the drums at each end of the combined revolving scutcher and hackle, in combination with the rings for preventing the hemp or flax from being drawn in at the ends, and around the journals or shaft of the same, as herein described.

We are aware that machines for beating, scutching, and cleaning hemp and flax have been made with rows of teeth on a cylinder, and therefore we wish it to be understood that we do not claim this as our invention; but what we do claim and desire to secure by letters patent, is the placing of the teeth, which are in rows parallel with the shaft, in the direction of a helix diverging from the middle of the length of the cylinder towards each end, for the purpose of spreading and acting upon every part of a bunch of hemp, as herein described.

GEO. W. BILLINGS,
JOHN HARRISON.

No. 4023.

What I claim as my invention, in the above-described machine, is arranging the metallic rings, composing the burring cylinder, so near together that no burs, or seeds, &c., can fall in between them; the rings having hooked teeth cut in the periphery, as described, and so placed around the cylinder as not to have the teeth on any two adjoining rings to come opposite each other, by which the wool or cotton is drawn in below the surface of the rings, and the seeds or burs are cleaned off.

Secondly, I claim the combination of the burring cylinder, constructed as above described, with the feeding cylinders and trash cylinder, to separate the fibres of cotton or wool from foreign or useless substances.

STEPHEN R. PARKHURST.

No. 4024.

Having thus fully described the nature of my improved machine for cutting up and crushing the ears of corn, and shown the manner in which the same operates, what I claim therein as new, and desire to secure by letters patent, is the combination of the drum and cutter, the cutter on the

case, and the regulating concave, so as to co-operate in producing the desired effect in the manner set forth.

I likewise claim the combination of the drum and cutter F, and the cutter G, on the case, arranged as above set forth, when used without the adjustable convave.

HIRAM A. PITTS.

No. 4025.

Having thus described my several improvements in the construction of the ordinary cylinder printing press, and shown the manner in which the parts thereof operate, what I claim as new therein, and desire to secure by letters patent, is, first, the manner in which I have combined the flying sheet frisket with the cylinder printing press, as set forth.

I do not claim the frisket as being new in itself, it having been applied to the bed and platen press, but never, as I verily believe, so modified as to adapt it to the cylinder press. I claim, therefore, the manner described of pressing the ends of the slats between the adjustable tape rollers, by which they are enabled to conduct the sheet on to the frisket in the position which it must assume in the cylinder press, said frisket being governed in its motion by the cam, arranged and operating substantially as herein made known.

I claim the lifting of the cylinder when it is desired that it should bear on the form as it revolves, such lifting being effected by means of the apparatus connected with the lever, arranged and operating substantially as described.

I claim the manner herein made known of constructing the spring box or apparatus used by me for checking the momentum of the bed in a cylinder press, but which may be advantageously applied in other machines for the like purpose; said spring box or apparatus being furnished with a céntre shaft, carrying a toothed wheel that gears into wheels or pinions on several surrounding shafts, the whole of which shafts carrying spiral springs, arranged and combined as herein made known, so as to co-operate with each other in the manner described.

RICH'D M. HOE.

No. 4026.

Having thus fully described the construction and operation of my improved double action ball pump, I would observe that I do not claim the pump-action, nor the working of two pumps together by one piston rod; but what I do claim as new, and desire to secure by letters patent, is the working of two pumps upon one rod, within one cylinder, in the manner set forth; the cross-piece attached to the piston rod, and passing out through the slats, in the cylinder, in the manner and for the purpose herein described.

FRIEDERICH WALTHER.

No. 4027.

Having thus described our invention, we shall claim the combination of the gauge punch, with a hopper arranged beneath it, and having a guide tube, or other suitable contrivance of like character, adapted to it, the whole being arranged and operated substantially as above described; also the

manner in which the bristles are fed beneath the gauge punch, as fast as it is necessary, when others are removed by the same from the hopper, viz: by means of the weighted strings, adapted to the hopper and frame of the machine, as above specified.

We also claim, in combination with the weighted strings, elevating the hopper when the gauge punch rises upwards; the same being for the purpose of drawing the strings over the bristles, and thereby insuring their movement beneath and into the fork of the gauge punch.

SAMUEL TAYLOR,
ALBERT R. DAVIS.

No. 4028.

What I claim is the combination, herein described, of the three levers L, M, and N, having a common centre in the lever, with the rod and the slides, and as a means of adjusting the slides while the engine is in motion, and the lever is working the slides by a reciprocating motion, or any combination substantially the same; but I do not claim the combination of, or the right to use the combination of adjustable slides and fixed seats, with openings for each end of the cylinder, as herein referred to, and set forth in letters patent granted to Horatio Allen, in August, 1841.

THOMAS ROGERS.

No. 4029.

What I claim as my invention, and desire to secure by letters patent, is the combination of the broad, high, cylindrical wheels, turning on separate axles, spreading out the surface or bearing so as to prevent sinking into the ground, with a locomotive steam engine or other driving power located on the carriage, as herein described.

JAMES SEMPLE.

No. 4030.

What I claim as my invention, and desire to secure by letters patent, is the bed pieces, and tabular pieces, with lateral projections, (figures 3, 4, and 5,) as used in combination with the iron piles aforesaid; also the method of protecting the bottom from abrasion, by means of the covering thereof, with the segments or triangular boxes aforesaid, expressed by figures 7, 8, and 16; also the combination of all these parts for the obtainment of permanent foundations in deep water, for the support of hydraulic structures.

I. W. P. LEWIS.

No. 4031.

Having thus fully described the nature of my improvement in the stove for heating apartments, and shown the manner in which the same operates, I do hereby declare that I do not claim as new the causing of the draught to descend through the fuel, this having been done before, though under an arrangement and combination of parts essentially different from that devised by me and herein described; but what I do claim as new, and desire to secure by letters patent, is the manner in which I have com-

bined and arranged the respective parts of my stove, so as to allow the burning coal to rest on the solid stove bottom, without a grate, the lateral opening for the escape draught being entirely above the bottom of the stove, and leading thence into the air heating chamber; by which device the radiation is increased, and the air for the supporting of combustion is also heated on its passage to the fire: the whole combination and arrangement being substantially the same with that herein described.

SAMUEL UTTER.

No. 4032.

Having thus fully described the nature and operation of my improved triple cylinder stove, what I claim therein as new, and desire to secure by letters patent, is the particular manner as above set forth, in which I arrange and combine the flue and air-heating spaces, and the pedestal of my stove, the hot air space being between the ascending and descending draught, the descending draught spreading around the base of the stove.

FRANCIS L. HEDENBERG.

No. 4033.

We do not intend to claim any of the parts used herein as our own and exclusive invention, because each taken separately has been already used for various purposes; but we do claim as new, and of our own *invention*, the *application* of the *vertical* hat block chuck on the mandrel, driven, in any convenient manner, beneath the bed, *in combination* with the movable arm, (m) secondary arm, (p) and descending arm, (q) with the chop piece, (r) when such application and combination are employed as the means of using the horizontal bush and flexible bush for the purpose of polishing and equalizing the nap, or pile, or exterior fibrous matter forming the surfaces of hats; the whole constructed and operating substantially as herein described.

JOHN LOUDON,
THOMAS SHAW.

No. 4034.

What I claim as my invention, and which I desire to secure by letters patent, is the making of the revolving skeleton cylinder, with combined swords and bars of teeth, for the purpose set forth.

W. Y. SINGLETON.

No. 4035.

I do not claim as my invention the impregnation of meat by hydraulic or other pressure, nor do I claim the modes of producing dessication; but what I do claim is the process, substantially as herein described, of curing meat by combining the operations of impregnation and dessication, in the manner set forth.

GEO. A. SCHERPF.

No. 4036.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the stirring rod, or bar, with the dropping bar or vibrating rod; and, in combination therewith, the gauge rod, with its index for regulating the amount of seed to be dropped, in the manner above described.

PIERPONT SEYMOUR.

No. 4037.

What I claim as my invention, and desire to secure by letters patent, is the machine for stuffing collars, as herein described; that is to say, the combination of the slides and wedges for stretching the collar, and, in combination therewith, the revolving table and hopper, constructed, arranged, and combined substantially in the manner and for the purpose above described.

I also claim, in combination with the form, the post and nut, sliding in guides for stretching the collar, as before made known.

WADE HAWORTH.

No. 4038.

What we claim as our invention, and desire to secure by letters patent, is constructing the former in strips, with a series of joints at or near the centre, as above specified.

We also claim the combination of a guard with the form over which the leather is to be crimped, the leather being placed between them to prevent the wrinkles, &c., as herein described.

We also claim the hooks in combination with the crimp, so as to be brought over the back of the former and pass through between the jaws, and taken out on the under side, as set forth, or they may be used in drawing up the leather and tack, &c.

We also claim, in combination with the above named guard and form, the bar in which are the screws, with a crank, for drawing up the leather, in the manner and for the purpose before specified.

REUBEN FAIRCHILD,
STARR FAIRCHILD.

No. 4039.

We claim, *first*, the manner of forming the knots by turning over the loops or meshes, already made into the form of a noose, across the whole net at once, as herein set forth, by means of a knot frame, constructed and operating substantially as described.

Secondly. We claim the manner of introducing the twine through the apertures of the nooses formed by the knot frame, by means of a needle, substantially the same as set forth in the description, in combination with the netting machine herein described.

Thirdly. We claim the manner of casting off the knots from the knot frame, and of tightening them by means of the action of the swivel, and bearing against the ends of the jacks, whilst the web of the previously formed net passes over the roller, and is held firmly in its position.

Fourthly. We claim the manner herein set forth of combining the parts

constituting the knot frame, consisting principally of the table, the counter table, three pairs of jaws attached to the table and counter table, each of which pairs of jaws is composed of two slips or pieces of metal, which are made to slide upon each other so as to open and close said jaws; the arrangement and combination of the plungers, P R, and *p r*, and of the connecting rods, by which said plungers and jaws are actuated, being substantially such as herein described and represented.

Fifthly. We claim the manner in which we have combined and arranged the jacks and the slur wheel with its carriage and their appendages, by which combination and arrangement the jacks are made to rise successively, and to draw the twine up so as to constitute a loop; the slur wheel being divided into four, or any preferred number of parts, and being moved on with the carriage, and actuated by a rack and pinion, substantially in the manner and for the purpose herein set forth.

Sixthly. We claim the manner of arranging, as formed, the twine comb, with its teeth or wires, to act against the rising meshes by the aid of the arm, acted upon by the pin in the wheel of the counter table, or in any other way that is substantially the same.

Seventhly. We claim the manner of combining and arranging the mesh frame, knot frame, twine comb, and their immediate appendages, so as to co-operate with each other, substantially as herein set forth, and for the purposes herein mentioned.

JOHN D. CORNELIUS,
JAMES MOTT, JR.

No. 4040.

What I claim, and desire to secure by letters patent, is the *lamp wick*, made or combined as above described, viz: with a strip of tape, muslin, Canton flannel, a piece of twine, or any other substance, and the candle wick attached or combined to the sides, as above set forth, or in any other way that is essentially the same, and for which I request letters patent.

Witness my hand this third day of April, A. D. 1845.

SAMUEL RUST.

No. 4041.

Having thus fully described the construction of our improved resting vat for flax or hemp, and the manner of regulating and diffusing the temperature equally through every portion of the contents of the same, while the retting process is in progress, we would remark, that we do not claim the retting of hemp or flax by means of hot or warm water, as that has been done before; but what we do claim as new, and desire to secure by letters patent, is the performing the retting process upon hemp or flax by keeping it immersed in water kept at a uniform temperature by artificial means, and that temperature not to vary more than twenty or thirty degrees from ninety of *Fahrenheit's* thermometer.

GEO. W. BILLINGS,
JOHN HARRISON.

No. 4042.

Having thus described my invention, I shall claim the combination of mechanical parts, by which the alternate elevation and depression of each of the impelling pawls which operate or give motion to the trough (through certain mechanism intervening between the said pawls and the troughs) are affected, the said combination consisting in the following parts, viz: the peculiar tilting box, (having projections to support the inner ends of the pawls and spring catches,) the weight M, (made to slide from one end of the box to the other end of it,) and the movable arms applied to the side of the trough; the whole being constructed, combined with the impelling apparatus and trough, and operating, substantially as above described.

In testimony whereof, I have hereto set my signature this fifteenth day of March, A. D. 1845.

JAMES M. WILDER.

No. 4043.

What we claim, therefore, as our invention, and desire to secure by letters patent, is the above described tools for forming hook headed spikes, and their application to said Osgood & Hunt's spike machine, which tools are so formed that when introduced into the movable die box of said machine, a projection is given to the dies, so that that part of the rod of which the head is to be formed receives the requisite bend in the operation of griping, as herein described, when the header described in Osgood & Hunt's specification of March, 1834, advances and completes the head.

JOHN F. WINSLOW,
his
ISRAEL × BLANCHARD.
mark.

No. 4044.

Having thus fully described my improvements, what I claim therein as my invention, and desire to secure by letters patent, is the combination of flues, as herein described, passing down on each side nearly the whole width of the stove, and contracting under the bottom and upon the opposite side, in the manner and for the purpose above set forth.

HENRY N. GROS.

No. 4045.

What I claim as my invention, and desire to secure by letters patent, is the mode of forming and printing the letters in stencil printing, or painting, by means of the combination of characters represented in the draught, and numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, essentially in the manner described, and the nine characters so represented.

E. B. FOSTER.

No. 4046.

What I claim as new and as constituting my invention, and desire to secure by letters patent, is the giving to the gaseous current a rotary mo-

tion around a central, conical, or other formed screw, by means of a spiral thread, or threads, combined therewith, which traverse the chamber, and form spiral flues around the same, whereby the sparks and other solid particles floating in the gaseous current acquire a centrifugal force that throws them off through proper openings, into an exterior chamber, while the gases escape through the central screen, as herein before set forth.

WM. C. GRIMES.

No. 4047.

I claim as my invention the intermingling and combining fibrous substances with the gum, in forming India rubber fabrics, solid and firm in the body, with a smooth surface, resembling leather.

NELSON GOODYEAR.

No. 4048.

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the drum and case with the smoke pipe, constructed and arranged, and operating, in the manner and for the purpose set forth, or other mode substantially the same for producing analogous results.

SAMUEL SWETT, Jr.

No. 4049.

What I claim as my invention, and desire to secure by letters patent, is the manner of feeding by means of the inclined feeding wedge, as before set forth; whether the operation be effected precisely in the same manner described, or in any other mode substantially the same.

I also claim the combination of the sizing gouge with the wheel and adjustable cutter, for the purpose and in the manner described.

M. W. ST. JOHN.

No. 4050.

Having thus fully described the improvement, what I claim therein as new, and desire to secure by letters patent, is the runner, constructed as herein described, having spiral wings thereon, from which project rows of pins, substantially in the manner and for the purpose herein made known, and in combination therewith; the grated concave as above set forth.

JANE A. DAVIS,
Administratrix of H. G. Davis.

No. 4051.

What I claim as my invention, and desire to secure by letters patent, is supporting the upper frame on and attaching it to the spindle on which the master-wheel turns, in combination with the mode of connecting the spindle with the lower frame by means of a turning platform, the master wheel being situated between the two frames; and there being no other connexion between the two frames than the said spindle, whereby the upper frame, which supports the belt wheels, may be turned in any direction without moving the under frame, as described.

I also claim connecting together the inner ends of the levers, by which the horses pull by joint link, the said levers being jointed to the master-wheel near its periphery, so that the horses shall perform their proportion of labor, as described.

ELIHU H. JAQUES.

No. 4052.

I do not claim the manner of effecting the elasticity of my pad by means of spiral springs, as that has before been done; but what I do claim as my invention, is combining with a pad, so rendered elastic, the cushion and stuffing thereof, in such manner that the central portion of the pad shall present a hard surface, while the portion exterior to said centre shall be of a soft, yielding nature, and at the same time exert a gentle pressure.

And I further claim, in combination with the above pad and cushion, making the concavo-convex plate project beyond the edges of the plate, so as to effectually prevent the cover of the pad from coming between the two plates, in the form and manner set forth.

DAVID B. W. HARD.

No. 4053.

What we claim as our invention, and desire to secure by letters patent, is the combination of the cross-levers with the rack and pawl, substantially as herein described. We do not wish to be understood as claiming this apparatus for a parallel motion; but, in combination with the bench-vice, as described, we believe it to be new.

We also claim the combination of the pawl for holding the rack with the nut on the screw of the vice, so that when the nut is pressed up in griping anything between the jaws, the pawl will act, and brace the lower end of said jaws in proper position.

W. H. TAYLOR,
A. P. NORTON.

No. 4054.

What I claim as my improvement, and desire to secure by letters patent, is the combination of the movable bar with the stationary teeth on the main cylinder, substantially in the manner and for the purpose above described.

THEODORE ELY.

No. 4055.

Having thus fully described my improvements, what I claim as new, and desire to secure by letters patent, is the combination of the movable balanced buckets with a water-wheel, having recesses to receive the inner ends of said buckets, in the manner and for the purpose above specified.

J. J. SPRINGSTEEN.

No. 4056.

Having thus fully described my invention in the bevel centrifugal water-wheel, and shown the manner in which the same operates, what I claim

therein as my invention, and desire to secure by letters patent, is the projecting of the beveled floats of the beveled centrifugal water-wheel up into the funnel-drift of the water in the scrolled penstocks, combined and arranged as described in the specification.

I do not intend to confine myself to the above sized wheel, which is suited only to the head and fall referred to, for the size of the wheel must correspond with the head and fall, and the inclination of the floats (which may be varied from ten to eighty degrees) must change accordingly.

JAMES LEFFEL.

No. 4057.

Having thus described our improvements, we shall only claim as our invention—

1st. The combination of the *bent lever griping jaws*, (arranged and operated by the toggles, &c., as specified,) with the movable sockets attached to the sliding frames; the whole being arranged and operating substantially as above described, and for the purpose of stretching the leather over the form.

Also, the combination with the above of a pair of pincers, capable of being applied to the leather at any point, and operated by means of a cord passing through the handles of the pincers, and attached to a revolving shaft, said shaft having a ratchet and catch, and the whole arrangement being substantially as herein before specified.

In testimony that the foregoing is a true description of our said invention and improvements, we have hereto set our signatures, this twenty-sixth day of March, A. D. 1842.

CHENEY SNOW,
THOMAS N. SADLER.

No. 4058.

Having thus fully described the nature and operation of my improvement on the above named machine for breaking anthracite or stone coal, what I claim therein as new, and desire to secure by letters patent, is the employment of pairs of rollers, to effect the breaking; one of which rollers, instead of being furnished with teeth, is perforated with holes, through which the broken coal is to pass, the other roller being provided with teeth corresponding with and entering a short distance into the holes in the first named roller, in the manner and for the purpose set forth; said rollers being geared together, and otherwise operating in the same manner as the within named machine of Joseph Baltin.

BENJ'N HAYWOOD.

No. 4059.

Having thus fully described my improvement, what I claim therein as my invention, and which I desire to secure by letters patent, is the method of using the rum, as above specified, in potting sugar; that is to say, by wetting each layer with the rum as it is potted.

I also claim the conical perforated tubes inserted into the hogshead, through which the molasses runs, which can be cleared by a stick, or otherwise, on the inside.

In witness whereof, I hereunto subscribe my hand before the witnesses under named.

IDE BRETTON, Sr.

No. 4060.

Having thus fully described the nature of my improvements in the spring latches and locks, what I claim therein as new, and desire to secure by letters patent, is the manner, herein described, of arranging and combining the piece which forms the spring-catch with the box of the lock, and with the stirrup by which it is forced forward; the said catch being attached to the box and to the stirrup by means of joint pins, so that its operation shall be substantially the same with that herein set forth.

JACOB ALRICHS.

No. 4061.

Having thus fully described the manner in which I construct my improved saddle, what I claim therein as new, and desire to secure by letters patent, is the converting the same into a spring saddle by means of a spring-bar of steel, bent into the form of the outer edge of a cantle, so that the straining girths may extend therefrom to the pommel, thereby giving elasticity to the seat, as set forth.

I likewise claim the manner of combining the stirrups with the saddle, by allowing the stirrup straps to pass over staples or rods, which are free from the saddle at the rear ends; by which device the stirrups will be detached from the saddle in case of their being drawn back by the falling of the rider, or otherwise.

I do not claim the forming of such staples or rods as new in the abstract, but limit my claim to their employment as a means of connecting the stirrups with the saddle, by which an important improvement is effected.

ROBERT CALDWELL.

No. 4062.

What I claim as new, and my own invention, in the within above described inkstand, is the introduction of a float, with a soft, yielding, or elastic upper surface, and so formed as to operate at all times, either as a stopper to the ink tube or a floating cover to and upon the surface of the ink in said stand, arranged substantially in the manner and for the purposes herein above set forth and described.

WALTER HUNT.

New York, *July* 12, 1844.

No. 4063.

What we claim as our invention, and desire to secure by letters patent, is the manner of arranging the pivots, in combination with the levers and bars, and guides or arms, operating in the manner and for the purpose set forth.

CHESTER STONE,
GEO. S. COLLINS.

No. 4064.

I do not claim the introduction of the smoke, heat, or other volatile products of combustion, to the sides of an oven, or a cooking range, through lateral flues proceeding from the boiling chambers; nor do I claim (as is claimed in certain letters patent numbered 3589, and dated May 17, 1844) carrying the lateral flues, or those proceeding from the boiling chambers, directly against the *front parts, or halves*, of the sides of the oven, and thence vertically, and thence horizontally *over* and in contact with the top thereof, and opening the same at the top of the oven into a discharge flue, in combination with carrying the main discharge flue of the fireplace beneath, and in contact with the underside of the oven, and around and in contact with the *rear parts*, or *halves*, *of its sides and top*, (whereby the rear parts of the sides are heated by the *central flue*, or that proceeding from the grate and under the oven,) and thence into the chimney or discharge flue; nor do I claim (as in my letters patent numbered 2990, and dated March 4th, 1843) causing the heat and smoke to circulate against the sides and bottom of an oven, by means of lateral flues proceeding from the boiling chambers and entering the sides of casing surrounding the oven, in combination with two horizontal and vertical partitions, arranged between the oven and its surrounding casing, by which the smoke and heat are caused to come in contact with the front part, *or a portion only* of each of the sides of the oven, and from thence to pass *underneath* the oven; but that which I do claim is the *particular arrangement* of flues on the *front* of the lower part of a chamber, on each *side* of the oven, and making it pass to the rear by means of a horizontal plate; thence upwards and over the plate, and towards the front of the chamber, and thence through an opening into the smoke chamber on the top of the flue plate, in *combination* with carrying the central flue of the fireplace directly under the bottom of the oven, upwards, and around its rear end, and over its top plate; thence into the before-mentioned chamber in the top of the flue-plate; by which arrangement I equally or uniformly spread heat over the whole of the sides of the oven by the action of the lateral flues alone, and *independently* of the central flue, for the purpose of heating the *bottom*, *end*, *and top* of the *oven* only; by which improved arrangement of central and lateral flues, I am enabled to gain certain very important advantages in baking evenly and without burning the articles in the oven, as I can apply a current of smoke and heat either to the whole exterior surface of the side of the oven, without making it pass against the top, rear end, and bottom thereof, and into the chimney, or I can make it pass in contact both with the sides, bottom, end, and top, and into the chimney, when desirable.

Also, I claim, in combination with the above, the making a narrow opening, or communication, between the side flues and central smoke flues at the top of the oven, for the purpose above set forth; the same being effected by extending the flanch plate down from the flue plate, and away from the oven, as above described.

In testimony whereof, I have hereto set my signature this 29th day of April, A. D. 1845.

MOSES POND.

No. 4065.

What I claim as my invention, and desire to secure by letters patent, is the combination of the following particulars: 1. The suspension of the carriage body or box upon vibrating arches. 2. The pin or guide, and its appendage, the semicircular hoop; and, 3. The swivel in the reach; all of which as herein described.

ARNOLD HOSMER.

No. 4066.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the apartments of the bellows by means of the flexible tube and the arrangement of the apertures and valves, as set forth.

WM. LILLIE.

No. 4067.

I claim the combination of the upright column or post, by which the showering apparatus is sustained while being elevated or depressed, with the portable box, as described; the said column consisting of the sections or pieces, having two dovetailed grooves in the front side of each of the sectional parts, &c., and each having a dovetailed tenon made to fit the dovetailed groove, as above set forth, and having a flexible cord or chain, with a screw and nut at one extremity and a head at the other, for drawing the parts together; the whole being constructed for the purpose of portability, and being packed within the bottom or reservoir, and operating substantially as above set forth.

I also claim the folding box, as herein set forth; that is to say, the two halves of said box, constructed with the side, when they are hinged, removable, and their edges that come together, when covered with India rubber, as herein set forth, or with other suitable substance, so that when they are opened, and the cambering cleats screwed on to the bottom, they shall form a water-tight joint, the reservoir being without any extension or partition across its central part, such as must exist if two boxes having two sides were employed, and which would interfere with the feet of the bather.

In testimony whereof, I have hereto set my signature this 26th day of April, A. D. 1845.

J. CUTTS SMITH.

No. 4068.

Having thus fully described my improvements in boot patterns, what I claim as my invention, and desire to secure by letters patent, is combining the plates, in the manner described, by means of the curved slot and straight slot, arranged in the manner and for the purpose set forth. I also claim the combination of the draught piece with the slide, in the manner herein specified.

I also claim, in combination with the front pattern, the separate pieces for measuring the toe and instep, as set forth; and, lastly, I claim the combination of the index *y* with the index on the toe piece E, for the purpose above specified

JOSEPH RIDER.

No. 4069.

What I claim as new and constituting my invention, and desire to secure by letters patent, is giving to the gaseous current a rotary motion around a cylindrical or other formed screen, by giving to the upper part of the chimney a curved, coiled, or convoluted form around the screen, substantially in the manner as herein before shown, as set forth.

WM. C. GRIMES.

No. 4070.

What I claim as my invention, and desire to secure by letters patent, consists in a mechanical arrangement, which so combines an index, constructed of cross hairs or spider-web lines, intersecting each other at right angles, or a dot on a plain lens, or any other similar contrivance, placed in the focus of the eye-glass of a telescope with a pencil, crayon, blunt point, or other marking implement, that when said index is apparently made to pass over the outlines of any object seen through the telescope, the said crayon, blunt point, or other marking implement, shall trace said outlines, as herein described.

ERASTUS WOLCOTT ELLSWORTH.

No. 4071.

We are aware that the hemp or flax has been broken or cleaned on a cylinder of knives, the whole set of beaters or breakers striking at once between the knives as they rotate, and therefore it will be understood that we do not claim this general character or principle; but what we do claim, and desire to secure by letters patent, is the arrangement of the beaters or scutchers to strike one after the other in succession, in combination with the continuous movement of the bed of knives or slats, as described and represented herein.

GEO. W. BILLINGS.
JOHN HARRISON.

No. 4072.

The parts of the above described machine which I claim by right of original invention, are—

First, the method of bringing the mould to and from the nipple by placing it upon what I call the crane, whose centres of motion are vertical, thereby allowing the mould a horizontal movement, as described; also, as forming part of the arrangement of this crane, the adjustable socket for the upper centre; also, as forming part of said arrangement, the slide, with rod.

What I claim as my invention, and desire to secure by letters patent, is the combination of the slide and rod with the horizontal moving crane, substantially as in the manner described; the crane receiving its reciprocating motion from the combination of the crank shaft, cam R, roller U, connecting link, rocking shaft, lever, and weight, or by other means substantially the same.

I also claim the arrangement of the adjustable socket for the upper centre

of the crane, as described, for adjusting the mouth of the mould to the orifice of the nipple plate, in combination with the crane.

DAVID BRUCE, Jr.

No. 4073.

What we claim as our invention, and desire to secure by letters patent, is the combination of the gang of knives or cutters with the roller, for cutting the threads or strips, according to the principle above described.

HORACE H. DAY,
HENRY G. TYER,
JOHN HELM.

No. 4074.

Having specified the characteristics of this wheel, and the manner of constructing the same, I wish it to be distinctly understood that I do not claim as my invention the form of the concentric part of the channels or water passages in the arms, nor simply making the arms eccentric, nor the employment of regulating valves at the issues of the channels, as these, separately, are well known; but what I do claim as my invention, and desire to secure by letters patent, is combining with the concentric, eccentric continuations of the channels, for the purpose and in the manner substantially as herein described; and I also claim the employment of the hinged and adjustable valves or shutters, which regulate and gradually reduce the capacity of the issues, and afford the ready means of removing obstructions from the channels, or water passages, in combination with arms having channels or water passages, of equal capacity, from end to end, as herein set forth.

T. R. TIMBY.

No. 4075.

Having thus fully described the nature and operation of my improvements in the mode of breaking and dressing hemp, &c., what I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the series of smooth, pressing, and bending rollers, revolving in the same direction, and with the same speed, for the purpose of loosening and separating the boon from the fibres, the same operating substantially as herein set forth; and these, thus combined and operating, I claim in combination with the holding rollers and beating cylinders, or either of them, substantially in the manner and for the purposes herein set forth.

RICHARD DEERING, Sr.

No. 4076.

I therefore claim as my invention the giving to the cutter a rotary motion on its axis, as it is carried around by the main shaft, as herein described, or in any manner substantially the same.

WILLIAM WRIGHT.

No. 4077.

Having thus fully described the manner in which I construct my stove, what I claim therein as new, and desire to secure by letters patent, is the combining of a cylindrical stove, furnished with a grate at each of its ends, with a drum, within which it may be inserted, in the manner and for the purpose set forth—the respective parts being constructed and arranged substantially as described.

CHARLES BABCOCK.

No. 4078.

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the arrangement of the flues, with the division plate, as set forth.

THEOPHILUS SMITH.

No. 4079.

What I claim as my invention, and desire to secure by letters patent, is the contrivance, as above set forth, for raking the ear on both sides of the centre, first down and then up. The arrangement, for this purpose, of the flanges, and their combination with the spurs of the wheel, I claim and wish patented.

JOSEPH D. BRIGGS.

No. 4080.

What I claim as my invention, and desire to secure by letters patent, is the screen, composed of strips of metal of a curved form, constructed and arranged as above specified.

I also claim constructing the cylinder and concave with wrought iron hoops, as described, projecting from the surface and fastened with staples that form teeth therein, in the manner and for the purpose above made known.

HENRY HIZER.

No. 4081.

What I claim as my invention, and desire to secure by letters patent, is a mode of constructing a submerged wheel for propelling boats with paddles, having a compound motion, such as to cause them to enter into and recede from the field of effective action edgewise, and, when out of the field of effective action, to move edgewise inertly from the point of recession to that of dipping, in the form and manner and for the purpose set forth in the foregoing specification.

SAMUEL B. HOWD.

No. 4082.

Having thus described my improvement, and its application to a piano forte, I shall state my claim as follows:

What I claim as my invention, and desire to secure by letters patent, is combining an additional octave string to each note of the piano forte, in the manner described; that is to say, by causing said strings to be raised, at the head or right hand end, a little above the strings that form the note, while at the opposite end they are depressed sufficiently to bring all the strings to a level at the point where the hammer strikes them.

I also claim placing the secondary bridge, or that nearest the right hand end of the instrument, in an opening made for that purpose in the plate, through which the bridge projects, a little higher than the one immediately in front of it; the hitch pins of the common strings being in that part of the plate that is between the two bridges, and those for the octave strings being beyond the secondary bridge.

I also claim the combination of the brace with the plate, for the purpose of supporting that part of said plate between the bridges; it being attached thereto by screws or otherwise, as herein fully set forth.

Lastly, I claim, in combination with the elevated strings, the crooked damper, in the manner and for the purpose described.

In testimony that the foregoing is a true description of my said invention and improvement, I have hereto set my signature this ——— day of June, in the year eighteen hundred and forty-five.

SIMON W. DRAPER.

No. 4083.

Having thus fully described my improvements, and pointed out their uses, what I claim as my invention, and desire to secure by letters patent, is the combination of a pattern, in any style for cutting garments, with scales for regulating the sizes thereof, substantially in the manner herein set forth.

S. B. STILLWELL.

No. 4084.

The improvement which I claim as my invention, and desire to secure by letters patent, consists in making a transparent concentrated or solidified jelly, containing all the ingredients so combined, concentrated, or solidified, that the article may be kept in a perfect state of preservation for any length of time, and be in a portable form for the supply of shipping, families, or for exportation, and requiring only the addition of the prescribed quantity of hot water to dissolve it when it, may be poured into glasses or moulds, and, when cold, will be fit for use.

PETER COOPER.

No. 4085.

What I claim as my invention, and which I desire to secure by letters patent, is the peculiar mode of combining the auger with the stationary base affixed to the timber to be bored, as described, so that a mortise can be bored in any direction of the compass of the machine without moving the base, by means of the frame, in which the auger is situated, sliding on ways to and from the standard attached to the base around which said ways revolve, and upon which they are elevated and depressed—the whole being

constructed and arranged substantially in the manner and for the purpose above made known.

JAMES B. COFFIN.

No. 4086.

What I claim as my invention or improvement, and desire to secure by letters patent, is the above described method of preserving food in hot places, seasons, or climates, in a *fresh*, *dry*, *cold air*, without the *immediate* presence of ice, or other cause, to produce *humidity;* and this I claim to do, either by creating a partial or almost entire vacuum, or by blowing or pumping in the air, in manner aforesaid; this fully and effectually causing *ventilation*, by air at a low temperature, and thereby better preserving from decay animal, vegetable, and other substances, liable to be destroyed by the presence of *heat* and *moisture*.

I also claim the right to construct, use, and vend the same, and to apply the coil of pipe, tubing, or cylinder, as also the air-pump, force-pump, or bellows, to vessels, or any apparatus already made and used, or intended to be made and used, as refrigerators, for the preservation of food, &c., in the manner aforesaid.

THOMAS H. KING.

No. 4087.

What I claim as my invention, and which I desire to secure by letters patent, is the mode of entrapping the drone bees in the lower box of chambers, within sight of and adjacent to the working bees, by means of the additional screen, in combination with the openings in the inclined bottom of the box, whose outlets are out of sight of the bees from the outside, and through which the drones are caused to pass from the inside of the body of the hive, as set forth.

I likewise claim the manner of extending the working capacities of the hive, by means of the inclined plane or way, and groove in the lower part of the frame, operating on the wheels, secured to the upper section of the hive, and the tongue or projection on the lower part of the base, on the principle of a wedge, and raising the upper section with the interior boxes sufficiently high from the lower section to admit the insertion of another box below the inner range of boxes, as set forth.

I also claim the arrangement of the entrance in combination with the drone trap, as described.

I likewise claim the combination of the inner tier of boxes with the outer range of hives, elevated by the inclined planes, as set forth.

CLARK WHEELER.

No. 4088.

In the foregoing described first and second variety of woof protection, I claim as my improvement, and desire the same secured to me accordingly, the hanging of the combs or limbs, before described, upon the race beam *itself*, in such manner as to sink to the face of the race as the lay moves back to admit the shuttle to pass smoothly over it, and rise immediately after, (if there be no woof thread,) bringing the protecting finger in contact

with the latch or cast-off, arresting the lay in its *first* downward progress, and *instantly* stopping the loom.

ENOCH BURT.

No. 4089.

What I claim as my invention, and desire to secure by letters patent, is—

1st. Making the external cone in segments, having adjustable metallic teeth or grinders between them, the said teeth being adjusted by the means above described, or any other substantially the same.

2d. The regulating the admission of the grain to the mill by means of the revolving gauge, as above described.

JESSE FITZGERALD.

No. 4090.

Having thus described our machine and its improvements, what we claim as our invention, and desire to secure by letters patent, is the combination of the bar and the toothed arms on the double-nut shaft running between the straight-toothed bars with the bark mill, constructed and arranged in the manner and for the purpose described.

A. P. NORTON.
MORRIS OWEN.

No. 4091.

Having thus fully described my improvements in sawmills, I wish it to be understood that I do not claim a self-setting sawmill, irrespective of the means used in effecting it, as that has before been essayed; but what I do claim as my invention, and desire to secure by letters patent, is the apparatus herein described for self-setting the log, and self-operating carriage motion; that is to say, the combination of the lever, bars, and cord, and shipper, with the sawmill, constructed and arranged in the manner and for the purpose herein described.

HENRY QUIN.

No. 4092.

What I claim as my invention, and which I desire to secure by letters patent, is the before described arrangement of the vibrating hand in combination with the revolving cradles, operated by the lever and eccentric grooved wheel or plate at the head of the axle of the cradle.

ERASTUS C. WEST.

No. 4093.

What I claim, and desire to secure by letters patent, is the arrangement and combination of the furnace and boiler, or other similar heating apparatus, with the drying and watering houses, railways, and watering apparatus, as above described.

I also claim as new, and as my invention, the peculiar construction of the watering-house, and the mode of managing the hemp, by putting in an

upright position on railroad cars, and subjecting it to the process of preparation, either in watering-houses or in pools of water, and while on the cars, and in an upright position.

I do not claim to be the discoverer of the mode of preparing unrotted hemp by the heating process: this is claimed by Mr. James Anderson, of Louisville, Kentucky, and I have referred to this method of preparation, in the manner above described, with his permission.

RICH'D DEERING, Sr.

No. 4094.

What I claim as my discovery, and desire to secure by letters patent, is the above process of preparing hemp or flax by first steeping it in warm water until it is completely macerated, and then, as soon as it has been brought to this macerated condition, the temperature of the water is to be immediately raised to or above the boiling point, by which means the further progress of fermentation and putrefaction is stopped; and by continuing the boiling of the water a rapid and complete separation of the gluten from the fibre is effected.

THOS. H. BARLOW.

No. 4095.

What I claim as my invention, and desire to secure by letters patent, is the aforesaid mode, and others substantially the same, of graduating the pressure of a truss by a screw, in combination with the additional plate or back, and main spring.

WM. R. GOULDING.

No. 4096.

These additions and modifications to and about the common ship anchor, and their application, for the purposes herein minutely described, are improvements which we claim to be of our own invention, which are briefly enumerated as follows:

1st, the method by which the cable is prevented from fouling upon the stock of the anchor, by attaching protections to the extremities thereof, which extend down and are fastened to the shank at a point below the trend of the shank. These protectors, from their oblique position, clear the cable whenever it touches it. They also obviate another difficulty which is frequently presented, when the anchor is lashed to the cathead, which secures in the entangling of the ropes, and the obstructing and tearing of the sails upon the portion of the naked stock which stands above the gunwale; this is prevented by warding off whatever comes in contact with it.

2d, the mode of protecting the arms of the anchor against the fouling of the cable, by means of movable plates of metals attached to the flukes by means of rings, or hinges, and covering the entire arm—the same being combined and operating as herein set forth. The inner ends of these plates move longitudinally upon ridges or projections made upon each side of the shank by means of a connecting chain or rope, by which, when the one plate is forced down upon the arm of the anchor, the other is drawn up to

a position at right-angles, or nearly so, with the shank; so that when the arm lies buried in the soil, the opposite one stands defended by the raised plate against the fouling of the cable, which plate assumes a position nearly perpendicular to the soil.

3. We also claim, for clearing the cable from off the arms of the anchor whenever it comes in contact with it, the combination of the hinged sliding plates with the two guards of the same curvature of the arms and crown, consisting of narrow strips of iron extending from fluke to fluke, and welded upon the sides of each. These guards are also attached to the crown of the anchor by means of a short shoulder, leaving a space between them and the arms of the anchor.

These guards, so situated, create a great width across the crown of the anchor, presenting a form as shown in fig. M, by means of which width, and the curvature of the guards, it is impossible to foul the cable effectually upon the arms, and it requires but the smallest force to cause the anchor to cant and bite the ground. The space left between the guards and arms presents a means by which the fish hook can be fastened about the guards or arms in such a manner as to fish the anchor.

N. P. ISAACS.
JAMES RAISBECK.

No. 4097.

As most of the parts herein described and employed have been used for other purposes, I do not intend to claim as new, or of my own invention, any of such parts, irrespective of the uses for which I have employed them, and therefore I limit my claims as follows:

I claim as new, and of my own invention, and desire to secure by letters patent, the manner of combining the barrel disks with the wheel, for the purpose of hoisting, lowering, or suspending weights by means of the ribs and grooves, or any analogous device; and I claim the further combination therewith of the means employed to govern and regulate the action of the said parts, namely, the friction bands g or g', and levers h or h', the attaching and detaching lever or rolling shaft and bit, 4 or 4', pin 3 or 3', and slide key 2 or 2', substantially as such manner and combination are shown and set forth, irrespective of the power employed to work the machinery, and also irrespective of the mode by which the power is connected to the working parts.

In witness whereof, I have hereunto set my hand, in the city of New York, this twentieth day of March, one thousand eight hundred and forty-five.

EPHM. MORRIS.

No. 4098.

The invention claimed, and desired to be secured by letters patent, consists in the arrangement of the day circle, with its index, in combination with the globe, mounted upon the oblique axis, and, in combination therewith, the calendar and analemma.

SILAS CORNELL.

No. 4099.

I claim the above new manufacture, or the combination of the two elas-

tic materials, stocking-knit fabric and caoutchouc, whether the latter be applied to the exterior surface or surfaces of said fabric, or between two or more pieces or layers of said fabric or cloth, substantially as set forth.

In testimony whereof, I have hereto set my signature this sixteenth day of June, A. D. 1845.

CHARLES GOODYEAR.

No. 4100.

' What I claim as my invention, and desire to secure by letters patent, is the mode of forming the spring-seat of the saddle by means of the springs hinged to the pommel, and the free ends of said springs moving or sliding in copper, brass, or other metallic grooves, or upon rollers of copper, brass, or other suitable metal, as set forth.

J. F. LEHR.

No. 4101.

What I claim as my invention, and desire to secure by letters patent, is the combination of the vibrating-box and convex washer placed therein, constructed, arranged, and operated in the manner and for the purpose set forth.

I likewise claim constructing the washer with an opening in the bottom, provided with a shutter for holding a part of a garment between the convex surface of the washer and the concave surface of the bed, whilst the body of the garment is within the box, as described.

HARRISON HAGANS.

No. 4102.

What I claim as my discovery, and the advantages of which I wish to secure to myself and my legal representatives, by obtaining letters patent, is the admixture or combination of coalaphane, either with asphaltum, or rosin, or pitch, or turpentine, or balsam, or prepared linseed oil, or caoutchouc, or with any of the materials known as rosins, gum-rosins, and bitumens, or with any two or more of them, and with lamp-black, or Frankfort black, or other dark-colored matter, in such due proportions as to form *printers' ink ;* and the proportions before given varied by the judgment of the manufacturer, according to the consistency of the mixed materials used, will be found to effect the object.

EDWARD CLARK.

No. 4103.

Having thus fully described the nature of my improvement in the manner of reducing those ores of iron which yield forty-five per cent. and upwards of that metal, and having also shown the manner of performing the same, what I claim therein as new, and desire to secure by letters patent, is the mode of manufacturing wrought or malleable iron in a reverberatory furnace, by combining said ores with carbonaceous matters in the proportions herein indicated, and in otherwise treating them, substantially in the manner above made known.

I also claim, in combination with the said process or manner of procedure, the reducing of pig or other cast iron to the malleable state, along with the ore which constitutes the original charge, as herein described; this latter claim being specifically limited to the reduction in combination with the process referred to in the first claim above made.

WILLIAM NEALE CLAY.

No. 4104.

What I claim as my improvement on the hydro-oxygen blow-pipe, and in the processes for supplying this instrument with gas, and desire to secure by letters patent, is as follows:

In the first place, I claim the employment of more than one jet pipe, or several jet pipes, so associated as to produce a large flame by the combination of several smaller flames or jets; or of one jet pipe, so crammed with coarse wire as to cause the gaseous mixture to escape into the air at the point of efflux in several jets, as already described, in lieu of one, as in using the instrument originally invented by me, and in all subsequent modifications prior to the one for which I now desire a patent; for, although in the concentric pipes used first by me, and afterwards by Daniells and Maugham, the hydrogen escaped from the pipe so as to mingle with the oxygen passing out through another, still, more than one pipe or one aperture yielding one jet was not used for the efflux of the mixture of the two gases employed. Moreover, although tubes, crammed with fine wire, have been employed as safety-tubes to prevent the retrocession of the flame, coarse wires have never been heretofore used to cram the tube at the point of efflux, so as to divide the gas at the place of inflammation.

I also claim the employment of a jet, which may be made from between two flat surfaces, whether channelled or not, or, in other words, from a fissure or keef, or row of holes, as set forth.

I likewise claim the refrigeration of the jet pipe or pipes, by passing it or them through a case or box filled with water or other refrigerating substances, as heretofore described and represented in plate 1, figure 3.

I claim, also, the employment of a vessel provided with a tray and rod, like that last described, in combination with another vessel of the same capacity, of which the bottom is above the middle of that first mentioned, both vessels communicating by means of adequate pipes and cocks, so that the gas may pervade both simultaneously, or, by shifting a cock, may be prevented from reaching the additional vessel; after which, the acid being driven into the second vessel, its contact with the zinc is prevented or diminished, as more fully made intelligible by the accompanying description and drawings.

I further claim the employment, for the support of the platinum, of a brick, of kaolin or other infusible earth, resting on a platform so balanced on a point, or a ball, or in any other way, as to be kept horizontal by attaching to it a weight, and supported by a lever twining on a universal joint, and as represented in plate 2, and heretofore described.

I claim, also, the employment of any variety of carburetted hydrogen for the fusion of platina, in lieu of hydrogen, in the apparatus above described.

ROBT. HARE.

No. 4105.

Having thus fully described the arrangement of the respective parts of my improved fan mill, and explained the operation thereof, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged the screen and the chess-board, and combined them with the screens ordinarily used, so as to obtain two distinct currents of wind, and to subject the falling grain to the stronger current below the screen and chess-board, thereby blowing off the heavier portions of foreign matter, whilst the chaff is blown off by the ordinary currents in the upper compartments of the shoe.

ISAAC T. GRANT.

No. 4106.

Having thus fully described the manner in which I construct, combine, and arrange the respective parts of my self-adjusting screw finisher, what I claim therein as new, and desire to secure by letters patent, is—

First, the manner in which I arrange the horizontal ring or zone, and its surrounding tubes, for receiving the blanks, in combination with the apparatus by which said ring or zone is made to revolve to the requisite distance to bring a fresh blank opposite to the cutter after a screw has been finished.

Secondly, I claim the manner in which I have combined the cam-wheel, the vertical cutter, slide, and the lever thereon which sustains the cutter, so that the respective parts shall co operate, substantially as set forth.

Thirdly, I claim the gauge wheel, with the inclination of its projecting rim, and the recesses thereon, in combination with the spring lever upon which said rim operates, by which the cutter is brought into contact with and removed from the blank which is being cut, as described.

Fourthly, I claim the manner in which I have combined the stationary and sliding frames of the screw-driver with the vertical shaft, and with the lever which bears on the revolving ring, so as to raise and lower said screw-driver, in the manner and for the purpose herein set forth.

And it is to be distinctly understood that I do not intend by the foregoing claims to limit myself to the precise arrangement or form of the respective parts as herein represented, but vary these as I may think proper, whilst I attain the same end under an arrangement and combination substantially the same.

CULLEN WHIPPLE.

No. 4107.

Having thus fully described the nature of my improved ditching and road plough, and shown the manner in which the respective parts thereof operate, what I claim therein as new, and desire to secure by letters patent, is, first, the manner in which I have combined the wheel and the lever, or tiller, with the beam of the plough, for the double purpose of guiding and of raising or lowering the fore-end of the mould board, as set forth.

I claim the manner of combining and arranging the wheel with the plough, by means of its cranked shaft and treadle, thereby enabling the attendant, who rides upon the seat, to raise the rear end of the mould-board, and to depress the point, as described.

I also claim the combining of the horizontal wheel, and the plank, or

piece which it sustains, with the plough, thereby enabling the instrument to form a trench of increased width, when required.

DANIEL S. STAFFORD.

No. 4108.

Having thus fully described my apparatus, and the process of manufacturing sugar, what I claim therein as my invention, and desire to secure by letters patent, is—

First, I claim the method of renewing or restoring the animal charcoal, as herein set forth, by means of the revolving cylinder, placed over two fires, in the manner specified, by which it is heated gradually to the proper temperature.

Second, I claim the employment of a series of horizontal tubes, placed one above another in the manner described, having a current of steam passing through them, and the cane-juice flowing over their exterior surface, by which the steam is condensed, and the juice is somewhat concentrated; thus serving the double purpose of a condenser and an evaporater, as herein before described; said condenser being attached either to the vacuum pan or exhaust pipe of the steam engine.

C. L. DEROSNE.

No. 4109.

What I claim in the above as my invention is the combination of a coupling lever, which, together with its support, is capable of being moved up or down, or not, as the case may require, and its wires TT, and regulating buttons or nuts, (*p h* of keys B and C, or *g p* of keys B and A,) and a lever, and auxiliary hopper or fly, (or other substitutes of like character,) applied to any two keys or key levers of a piano forte, for the purpose of sounding the strings of both keys by striking upon one of the keys, as above described.

And I also claim the combination with the hopper which is applied to the key levers, for the purpose of elevating the parts above, and the hammers of the vibrating bar or apparatus, by which said hopper is thrown out of action, upon the parts above it, the same being for the object or purpose, as herein before specified.

And I also claim the mechanism of combination, by which I am enabled at pleasure to effect the action of a key above or below the key struck by the performer, the said mechanism consisting in the movable board, made capable of being raised or lowered by pedal levers, the respective regulating buttons or nuts *p h* of the keys B and C, and *g p* of the keys B and A, the said nuts being arranged upon their wires, and the whole of the said mechanism being operated and applied to the other parts of the action substantially as described.

In testimony whereof, I have hereto set my signature this eighth day of April, A. D. 1845.

SAMUEL R. WARREN.

No. 4110.

What I claim herein as new, and desire to secure by "letters patent," is

the discovery of the peculiar principle or feature exhibited in the accompanying drawings and specification, to wit: Regulating the bed or platen of toggle joint and other presses (to suit various sized bales or packages) by its connexion with some moving part of, or connected with, the press, and the *holding* said platen at *any* and *all points* of its range, with equal power or force of resistance, as is indicated by the position and power of the press, and in accordance with the size of the bale, using for that purpose any known mechanical arrangement that will produce the intended effect, as herein set forth.

S. W. BULLOCK.

No. 4111.

I am aware that conical propellers have been heretofore proposed to be used, but these differed materially from that herein described, they having been furnished with propelling vanes, buckets, or threads, set spirally on the outside of the cone; and to such propellers I do not therefore make any claim; but what I do claim as new, and desire to secure by letters patent, is the within described manner of forming a propeller for steamboats and other vessels, by placing vanes or buckets within a hollow cone, which is made to revolve with its open mouth, or base, in the direction of the vessel's wake, and its apex pointing towards the bows; the whole combination and arrangement of the respective parts being substantially the same as those herein set forth.

HORATIO HUBBELL.

No. 4112.

I wish it to be understood that I do not claim the mere addition of a separate casting or shoe to prevent wear; but, having thus fully described my improvements, what I claim therein as my invention, and desire to secure by letters patent, is the combination of the shoe with the mouldboard of the above described plough, in the manner and for the purpose described, so that the plough shall always run in the proper position.

SAMUEL SHEARER.

No. 4113.

What I claim as my invention and improvement, and desire to secure by letters patent, is the combination and arrangement of the mould-boards H and I, formed in the manner and for the purpose above described, with the twisted bottom, and wing, and base, and adjustable cutters, as herein before described. I make no claim to the other parts of the machine, as they are common to all ditching machines.

ROBERT COMMINGS.

No. 4114.

What I claim as my invention, and desire to secure by letters patent, is the combination of the revolving beating cylinder, movable and adjustable rest, and hinged concave, all arranged and operating with the flue and

screen, substantially in the manner and for the purpose described and set forth.

COLEMAN C. ESTES.

No. 4115.

What we claim as our invention, and desire to secure by letters patent, is the combination of the spring pulley with the cylinder of the threshing machine, as above described.

We also claim the spring beaters, as above described.

Thirdly, the changeable or movable frame, as described.

Given under our hands this sixteenth day of May, 1845.

JOHN T. WARREN.
EDMUND WARREN.

No. 4116.

What I claim as my invention, and which I desire to secure by letters patent, is the manner in which I construct my hive, as before described; that is to say, placing the small boxes, usually called the honey boxes, below the main hive and entrance, substantially in the manner described; the mode practised by all others being to place the honey boxes above the entrance for the bees.

ELIAS PARKS.

No. 4117.

What I claim as my invention, and desire to secure by letters patent, is the manner of combining the plates with each other, and with the box, the whole being constructed, arranged, and operates, as above described, and substantially for the purpose set forth.

AUGUSTUS HAMANN.

No. 4118.

Having thus fully described my ventilating hat, what I claim as new therein, and desire to secure by letters patent, is the combination of the perforations in the side of the hat and lining, surrounded and protected by a metallic plate on the outer side, the adjusting plate for opening, closing, or regulating the size of the apertures in the same, with the open or wire banding covering the same; all arranged and operating substantially as herein described and set forth.

In testimony whereof, I, the said John N. Genin, have hereto subscribed my name, in the presence of the witnesses whose names are hereto subscribed, on the twenty-seventh day of May, A. D. 1845.

JOHN N. GENIN.

No. 4119.

Having thus fully described our improvements, what we claim therein as new, and which we desire to secure by letters patent, is the combination of the fireplaces with the flue, constructed, arranged, and combined in the

manner and for the purpose set forth; the pipe which connects the fire *a* with the fire *b* being made to divide the descending flue.

And we also claim forming the flue under the stove, in the manner described, so that the draught shall be principally thrown to the sides, without being entirely cut off in the centre.

ELIAS JOHNSON.
DAVID B. COX.

No. 4120.

Having thus described our machinery, we shall state our claims as follows:

What we claim as our invention, and desire to secure by letters patent, is the method, herein above described, of copying or forming the longitudinal irregularities of piano legs, and other similar articles, on rough blocks of wood, by means of a carriage moving *horizontally* against the *revolving* cutter, and holding both the pattern and the rough, the cutting tool being raised and depressed, for depths of cut, by rollers resting on the patterns, the whole method or *modus operandi* being substantially as herein set forth.

In testimony that the foregoing is a true description of our said invention, we have hereto set our signatures, this eighteenth day of April, A. D. 1845.

WARREN HALE.
ALLEN GOODMAN.

No. 4121.

What I claim as my invention, and desire to secure by letters patent, is the combination of one of the steering ropes with the spring bolts, through the medium of the balance lever, or its equivalent—substantially in the manner and for the purpose herein set forth.

JOHN T. KIMBALL.

No. 4122.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is the cutting holes through the body and lining of the hat, and leaving the outside plush whole, or merely piercing it without cutting away any portion, so that the nap shall cover said holes, and render them invisible on the outside, while a free circulation is maintained through the hat, as described.

I also claim, in combination with a hole or holes in or near the top of the hat, a hole or holes at some distance down the side of the hat, just above the top of the head, to cause a circulation through the hat, as set forth.

I also claim the combination of the ornamental cup with the hat, as described, which allows ventilation unobstructed, and prevents the rain from entering.

G. W. CHERRY.

No. 4123.

What I claim as my invention, and desire to secure by letters patent, is the combination of the reciprocating carriage with the pressure rollers, in the manner described, so as to give the pressure both ways, in the manner set forth, by which brick is made either from crude clay pulverized, or sand or slop brick is manufactured.

J. PARSONS OWEN.

No. 4124.

I claim as my invention the employment of a series of tubes or pipes, having projections and pinions (with or without teeth) placed at intervals along the length of pipes or tubes as above described, and a piston having a "rack" attached, and a "rack" attached to the carriage or carriages, or vessel or vessels, to be propelled, or any like or similar arrangements of a "rack," or "band," or "rope," which might be made to act in like manner upon the said pinions or upon each other, to produce the effect, as above described, upon an atmospheric railway. I do not claim any of the separate parts of my apparatus, all or some of them being well known; but I claim the same in combination, for the purpose of carrying out practically and effectually my method of propelling by the effect of the natural atmosphere; but I do not confine myself to the precise arrangements above set forth, as some may be found surperfluous in practice, or modifications of them may be desirable.

I claim the use of the flat or conical seat on the axis of my pinions, to form a valve for the admission of air, and for making an air-tight joint, in combination with my main pipe or tube, as set forth.

In witness whereof, I, the said James Pilbrow, have hereto set my hand and seal this third day of April, 1845.

JAMES PILBROW.

No. 4125.

What I claim as my invention, and desire to secure by letters patent, is the combination of a water-wheel, which rises and falls with the current or tide, with an endless chain and pulleys, in the manner and for the purpose above specified.

R. C. GRANT.

No. 4126.

Having thus fully described the nature of my improvement in re-action water-wheels, what I claim therein as new, and desire to secure by letters patent, is the manner of forming one side of the water ways and issues of such wheels so that they shall yield and increase the width of the issue, for the purpose and in the manner herein set forth.

JOSHUA EVERED.

No. 4127.

What I claim as my invention, and desire to secure by letters patent, is the loose points upon the upper side of the share, being connected to the

share by means of a dovetail, or other analogous device; I also claim the invention of a plough having one or more points between the forward point and the back end of the cutting part of the share, whether cast fast to the share or loose, as per drawings annexed, substantially in the manner and for the purposes set forth.

WM. BULLOCK.

No. 4128.

Having thus fully described the nature of my improvement in the re-action water-wheel, what I claim therein as new, and desire to secure by letters patent, is the delivering of the water from a penstock or trunk, into the issues or buckets, a re-action wheel that revolves vertically at the lower part only of said wheel, by forming the opening from such penstock or trunk so that it shall enter such wheel at its lower part only, in the manner and for the purpose set forth, by which construction and arrangement I am enabled to give any desired diameter to such re-action wheels.

ABNER CHAPMAN.

No. 4129.

Having thus pointed out the characteristics or principles of my invention, and the manner of making and using the same, what I claim as my invention, and desire to secure by letters patent, is the arrangement of the various passages leading to the hive, and in combination therewith the chambers with honey-combs, surrounding the passages, for the purpose, as fully expressed above, of preventing the entrance and detaining the miller, moth-worm, and other insects, as herein fully described; and I also claim, in combination with the passages and the chamber, the additional moth or insect trap, situated relatively to the entrance passages, as herein described.

ABRAHAM DECKER.

No. 4130.

Having thus fully described my method of forming matrices for casting the face of printers' type, and other articles therein, what I claim as new, and desire to secure by letters patent, is the manner of forming the same by means of a common type or cut, and a metallic plate with an opening, with slanting sides, the two arranged and prepared in the manner herein described, and placed in a solution of sulphate of copper, and connected with the pole of a galvanic battery, in the same manner usually practised in electrotyping; and after receiving a sufficient deposite of copper, to be fitted up for use, in the manner herein set forth.

THOMAS W. STARR.

No. 4131.

What I claim as my invention, and desire to secure by letters patent, is the combination of a valve with artificial nipples, as herein set forth.

ELIJAH PRATT.

No. 4132.

What I claim as my invention, and desire to secure by letters patent, is the manner or method of cementing or welding tortoise or turtle shell in the shape or form of keyed bugles, by winding with cord or twine, and steaming it, and making keyed bugles from that article, as before described.

GEO. W. SHAW.

No. 4133.

Having thus described my improvements in hot-air furnaces, I shall state my claims, as follows:

I do not claim simply making the top of the fire chamber dome-formed, nor do I claim the combination of an outer and inner hot air chamber; but what I do claim as my invention, is connecting the cylinder of the fire chamber with the central hot-air chamber, by means of a dome-formed top, and discharging the hot air through the middle thereof, whereby the air of the inner and outer chambers is more effectually brought into contact with heated surfaces than in any other arrangement heretofore known.

I also claim making the cast-iron top plate of the ash pit, with cells filled with non conducting substances, for the bottom of the fire-pot to rest on, and thus prevent the said plate beyond these cells, where it forms the bottom of the air chamber or chambers which surround the fire-pot, from being cracked by the heat, which would otherwise be conducted from the fire-pot to this plate, as described.

In testimony that the foregoing is a true description of my said invention and improvement, I have hereto set my signature this first day of August, in the year eighteen hundred and forty-four.

GARDNER CHILSON.

No. 4134.

Having thus fully described the manner in which I construct my abdominal supporter, for the cure or relief of *prolapsus uteri*, what I claim therein as new, and desire to secure by letters patent, is the combining with the hypogastric or abdominal pad a spring lever, such as is shown at B B, in the accompanying drawing, in such manner as that it may be used to increase or diminish the pressure on the lower part of said pad, by an arrangement substantially the same with that herein fully made known.

EPHRAIM COLVIN.

No. 4135.

We do not claim to have invented any of the parts herein described, as all are already in use, and well known; neither in our arrangements, as above described, do we claim to have obtained any results not contemplated or sought for by others, our claim being only for obtaining an increase of equality in the performance of watches, chronometers, and other timepieces, first, by the mode we have described and shown of forming the balance rim with quarter circles, arches, or segments, each way from each end of the arm, instead of a half circle from each end in opposite directions; and, secondly, by the application of a second balance spring above, below,

or inside the single balance spring heretofore in use, substantially as the same are described and shown.

In witness whereof, we have hereunto set our hands, in the city of New York, this twenty sixth day of May, one thousand eight hundred and forty-five.

JOHN BLISS.
FRED. CREIGHTON.

No. 4136.

What I claim as my invention, and desire to secure by letters patent, is the combination of a bow of wood, to fit the neck of a horse or mule, with the mode herein described of ironing and padding the same, so as to constitute the harness, collar, and hames, all complete in one.

F. C. CURTIS.

No. 4137.

Your petitioner further represents that he claims as his invention, and desires to secure by letters patent, the following particulars and combinations:

1st. An elliptical covering in combination with the circular oven, allowing the heat to act with more uniformity on all parts of the oven, and affording the draught an opportunity to unite and pass off freely.

2d. The manner in which I have combined and arranged the valves *k* and *i*, with respect to the draught pipe L, and boiler holes, and, in combination therewith, the two division plates extending back on each side of the valves in the centre of the stove.

JEHIEL F. FARRAND.

No. 4138.

What I claim, and desire to secure by letters patent, is the contractile valves to sucking and air-tubes of nursing bottles; and also the application of artificial nipples to the same, as herein set forth.

ELIJAH PRATT.

No. 4139.

Having thus fully described the nature of my improvement in clocks or timepieces, and shown the manner in which my friction preventer operates, what I claim therein as new, and desire to secure by letters patent, is the employment of a suspension piece, arranged and operating substantially in the manner of that which I have denominated the friction preventer, for sustaining the weight of the balance wheel and its arbor, as herein fully made known.

ELI TERRY.

No. 4140.

What I claim as my invention, and desire to secure by letters patent, is the obtaining of additional heating surface, and causing a lengthened cir-

culation to the flame, smoke, and heat within an enclosure of metal or walls of a hot-air furnace, without any downward draught, by the means of a system of tubes; combined, arranged, and situated as above described.

ADRIAN JANES.

No. 4141.

I shall therefore claim the combining with the space directly beneath the orifices of discharge of the gas, and with the supply or branch tubes, an expansive chamber, so as to operate in the manner and for the purpose herein before set forth.

I also claim making the lower part of the inner cases of the burner with a bell-shaped opening or mouth, in the manner and for the purpose as above specified.

In testimony whereof, I have hereto set my signature, this twenty-third day of May, A. D. 1845.

WM. BLAKE.

No. 4142.

Having thus fully described my machine, what I claim as new, and desire to secure by letters patent, is constructing the cover of the saddle in such a way as to allow the tree to be stuffed, or covered with stuffing, by making said cover in one piece, so as not to present the projection of jockeys, or small skirts, or the ridges occasioned by draw-downs, &c.

BENJ. SUITS.

No. 4143.

What I claim as my invention is the above described improvement, or manufacture, or combination of a colored sheet of test paper and one or more plain white, or lighter, or darker, or different colored sheets or surfaces of paper, applied to one or both sides of the test sheet, substantially as above specified.

ARTHUR VARNHAM.

No. 4144.

What we claim, therefore, as our invention, and desire to secure by letters patent, is the manner herein described, in which we have arranged and combined the respective parts of the apparatus for salting or impregnating provisions with any desired solution, as set forth; that is to say, we claim the combining of a common lifting pump, and of a force pump, with the vessel and with the cistern, substantially in the manner and for the purpose herein fully made known.

DION. LARDNER.
JAS. DAVIDSON.

No. 4145.

What we claim is constructing a reflecting baker, in the form as above described; that is to say, the baker of a cylindrical form, having the grate

or shelf upon which the articles are to be cooked being placed near the centre, in the manner above described.

VALPARAISO, PORTER COUNTY, IA., *July* 23, *A. D.* 1845.

WILLIAM TAINTOR.
HARLOW S. ORTON.

No. 4146.

Having thus fully described my machine for hulling and cleaning clover seed, what I claim as new, and desire to secure by letters patent, is, first, the grooved form of the projections upon the beating cylinder, and surrounding concave, the grooves being either circular, as in figure 3, or spiral.

I also claim the manner in which the beating and perforated concaves are connected by the double apertures, and, in combination therewith, the form of the discharge aperture for the chaff; all combined, arranged, and operating substantially as herein set forth—not confining myself to the exact forms and proportions herein represented, but the general principles of the machine.

SAMUEL W. POWELL.

No. 4147.

We are aware that machines for cutting laths have been made with a carriage to carry the bolt or block against the edge of a knife, and that the bolt or block has been griped preparatory to and during the operation of cutting, in machines in which the knife is carried against the bolt, instead of the bolt against the knife, and the bolt liberated before the knife has been moved back clear of the bolt; and hence we wish it to be clearly understood that we do not claim to be the original and first inventors of these; but what we do claim as our invention, and desire to secure by letters patent, is making the carriage which carries the bolt or block to the knife in two parts, moving on each other, and connected together by a spring, or analogous device, so that the bolt is griped whilst being carried against the edge of the knife, and still griped until drawn back of the edge of the knife, and then liberated, for the purpose and in the manner substantially as herein described.

SOLOMON F. FINCH.
JAMES WHEELER.

No. 4148.

What I claim as my invention, and desire to secure by letters patent, is making the grinding teeth of mills in concentric rows, projecting from the surface of the plates, so that the teeth of one plate shall run in the spaces between the teeth on the other, and vice versa, in combination with the grooves or furrows running towards the periphery of the plates, through which the substances acted upon are carried outwards, whether these furrows be arranged radially, according to what is technically termed the eight-quarter dress, or in other manner, leading from the inner to the outer range of teeth.

And I also claim in combination with the teeth, arranged as expressed in

the above claim, the breaking teeth on a cylinder or cone, arranged substantially as herein described and for the purpose specified.

BERIAH SWIFT.

No. 4150.

What I claim as my invention, and desire to secure by letters patent, is the combination of the external textile tube with the entire India rubber tube, as above described.

HORACE H. DAY.

No. 4151.

Having thus fully described the manner in which I construct my lock, and explained the operation of the respective parts thereof, I do hereby declare that I do not claim to be the inventor of a key with an expanding bit drawn out by an eccentric, this having been before used; nor do I claim the employment of a series of tumblers or levers, which are to be raised to different heights by the key bit, these being also well known; but what I do claim as constituting my invention, and desire to secure by letters patent, is the particular manner in which I have combined and arranged certain parts of my lock, by which combination and arrangement a new and useful effect is produced; that is to say, I claim the manner in which I have combined the key, having an expanding bit, with the revolving box or drum, the latter being equal in thickness to the bit of the key, and having a key-hole through it by which it is turned with the key, in the manner and for the purpose set forth.

I claim the manner in which I have combined what I denominate the pressure tumbler, carrying the stump with the ordinary tumblers; the pressure tumbler having its fulcrum pin on the lock bolts, and the ordinary tumblers their fulcrum pin attached to the box of the lock, and also having their fore-ends provided with projecting teeth, for the stump to act upon, in the manner and under the conditions set forth; the whole arrangement and operation being substantially the same with those herein described.

ANGUS McKINNON.

No. 4152.

Having thus fully described the nature of my improvements, in the manner of constructing cooking stoves, what I claim as new therein, and desire to secure by letters patent, is, first, the manner in which I arrange and combine my dampers, so as to close the opening for the admission of heated air to the cavity in the oven door, and to be opened by the closing of said door, as set forth.

Secondly, I claim the manner of arranging and combining the semi-cylindrical dampers with the flue spaces of the stove, for the purpose and substantially in the manner herein made known.

HOSEA HUNTLY.

No. 4153.

Having thus fully described my improvement, what I claim as my in-

vention, and desire to secure by letters patent, is the combination of the inclined plane with the washer or piston, constructed and arranged in the manner and for the purpose set forth.

HARVY W. SABIN.

No. 4154.

Having thus fully described the nature of my improvement in the lamp for burning lard and other fatty substances, what I claim therein as new, and desire to secure by letters patent, is the employment of a wick receiver, which is attached to the lower end of the wick tube or tubes, for the purpose of containing a length of wick that may be coild up therein, in the manner and with the intention herein made known.

ANDREW KAYSER.

No. 4155.

What I claim as my invention, and desire to secure by letters patent, is the connecting of the claw to the handle, as above described, with the loop at the end for the handle to pass through.

SOLOMON ANDERSON.

No. 4156.

Having thus fully described the nature of my improvement in the eccentric revolving pivot chain, what I claim as new is the placing of the pivot or pin upon which the seat revolves at an equal distance from the two sides of the seat, and at two-fifths (or nearly so) of that distance from the back of the chair, as set forth, or at a point so near to that distance as shall be substantially the same in the result of its action.

JORDAN L. MOTT.

No. 4157.

What I claim as my invention, discovery, art, or improvement, and desire to secure by letters patent, is the art or process of separating the impurities contained in salt water or brine, in its crude state, by adding a sufficient quantity of common salt to the salt water taken from the salt springs, wells, or other source, in its crude state; when properly mixed and dissolved, to bring the brine in the vats or cisterns to immediate saturation, for the express purpose of precipitating the impurities and depositing them in the bottom of the vats or cisterns, without the aid of evaporation or of solar or artificial heat. I do not claim adding salt to salt water, for the purpose of concentrating, as is frequently done; but I do claim the process, above described, of separating the impurities from salt water by the addition of salt thereto, allowing the impurities sufficient time to settle, and the drawing off for evaporation. Dated August 11, 1845.

NEHEMIAH P. STANTON.

No. 4158.

Having thus fully described the characteristics of my invention, and the

manner of making and using the same, I wish it to be distinctly understood that I do not make claim to the employment of a series of wheels having the same axis of motion when the sections of the shafts are separated from each other by a permanent sleeve, when the arrangement of the wheels is such as to cause the sections of the shaft to turn in reverse directions, as these are well known and do not attain the end contemplated by me, and pointed out above; nor do I claim simply oiling a journal through a perforation in the shaft, as this has long since been known; but what I do claim as my invention, and desire to secure by letters patent, is the arrangement of two sets of cog or belt wheels, and pinions connected therewith, each set consisting of not less than two wheels, with their appropriate pinions, on two shafts made in sections turning on each other, and in the same direction, for the purpose of avoiding friction, and rendering the machinery compact, as herein described.

And I also claim, in combination with the arrangement of shafts herein described, the oil passages, whereby the oil applied at two places is conducted to all the rubbing surfaces of the series of shafts and bearings, as herein described.

JAMES LEFFEL.

No. 4159.

What we claim as our invention, and desire to secure by letters patent, is the construction of a diving or descending flue at the end of the fire-box, communicating with the flue beneath an oven, placed immediately behind and upon a level with the fire box, or nearly so.

FRANCIS S. LOW.
JOHN S. LEAKE.

No. 4160.

What I claim as my invention, and desire to secure by letters patent, is the employment of an elastic metal tool for cutting and turning off, and shaping the periphery or sides of grindstones, as above described, in any form or manner substantially as herein described, in which an elastic metal tool may be applied to that use.

CHARLES ARTHUR.

No. 4161.

I claim the afore-specified combination of ingredients, whether in the proportions set forth, or in any other which may, under any circumstances, be found better applicable for the purpose intended.

In testimony whereof, I have hereto set my signature this eighteenth day of June, A. D. 1845.

SOLOMON GUESS.

No. 4162.

What we claim is the manner in which we construct the wash board, so as to effect a partial vacuum within its lower portion by centrifugal action, in the manner and for the purpose above described.

T. C. BENTON.
H. W. ZIMMERMAN.

No. 4163.

What I claim as my invention, and desire to secure by letters patent, is the apparatus for the lasting boots by the compound instep and shank draught, as herein above substantially described and set forth, by means of the above described machine, or any other substantially the same.

DAVID HARRINGTON.

No. 4164.

Having thus fully described my improvements, what I claim therein as my invention, and for which I claim letters patent, is the combination and arrangement of the springs, and the manner in which they are applied to the sliding board, and the rollers attached to the same, the use of which has heretofore been shown.

Lastly, I claim the mode of arranging the springs and handle for the purpose of relieving the standards on one side, as above made known, by coiling the springs around the arm that connects the handle with the standards, so that as the handle is raised above the top of the box to draw back the standards, the spring is relieved.

HORATIO HOSKINS.

No. 4165.

What I claim as my invention, and desire to secure by letters patent, is the combination of the arched jaws and curved spring, connecting bars, screw rod, and lever, arranged and operated in the manner and for the purpose set forth.

JOHN YOUNG.

No. 4166.

What I claim as my invention, and not before known, in the above described swing, and desire to secure by letters patent, is the application and use of springs in combination with the connecting rods, and in the construction of a swing, so that persons exercising thereon may receive the motion of a spring, in combination with the ordinary swing motion; and the manner of giving motion to the swing by means of the cord and pulley, or cords and pulleys, in combination with the swinging and stationary frames, as herein described.

JOEL H. ROSS.

No. 4167.

I do not claim as my invention the construction of galvanic rings of any description: what I do claim as my improvement, and desire to secure by letters patent, is simply making the galvanic rings, bands, &c., elastic, in the mode described.

DAVID C. MOORHEAD.

No. 4168.

What I claim as my invention, and which I desire to secure by letters patent, is the mode of preventing the moth from entering the hive, and entrapping her by means of the upright metallic tubes and inverted truncated cones forming the entrance to the reception room of the hive, and the upright tube forming a passage between the chamber and lower box, all of said tubes being surrounded by inverted truncated cones, and containing water, and into which the moth is caused to fall, as described.

I also claim combining with the vertical tube a spiral rest upon which the bees cluster, in the manner and for the purpose set forth.

ISRAEL LAMBORN.

No. 4169.

What I claim as my invention is the combination of the cylinder, included conical sieve, and fan, substantially as herein described, and for the purpose of cleaning grain.

And I also claim the combination of the cylinder, included cylindrical screen and fan-blower, substantially as described ; and also the combination of the cylindrical screen, conical sieve, fan blower, and cylinder, for the purpose and in the manner described above.

ANTHONY COOLEY.

No. 4170.

What I claim as my invention, and desire to secure by letters patent, is the manner of securing the cultivator beam to one of the cross-pieces of the handles or standards, (upon which it turns,) in combination with the manner of fastening and screwing the same to each other, and regulating the angle of inclination of the handles and cultivating points, and the position of the beam, by means of the adjusting braces and nuts, constructed and operating substantially in the manner and for the purpose herein set forth, and represented in the different modifications of my new and improved shovel-pointed cultivator.

ALMOND HARRISON.

No. 4171.

What I claim as my invention, and desire to secure by letters patent, is the attachment to the rear of the plough of the adjustable hinged shoe, guiding cutter attached thereto, and adjusting brace ; all combined and operating substantially in the manner and for the purpose herein set forth.

I also claim the attachment to the plough standards and shafts of the lateral adjusting braces, substantially in the manner and for the purpose herein set forth.

ANDREW RALSTON.

No. 4172.

Having thus fully described the nature of my machine for breaking coal, and shown the manner in which the same operates, what I claim therein

as new, and desire to secure by letters patent, is the manner, herein made known, in which I form and combine the bars, and the wheels working between them; the bars having the cutters projecting out laterally from them, and the wheels carrying the cutters on their peripheries.

I do not make any claim to the manner of gearing this apparatus, nor do I intend to limit myself to the particular mode of so doing, herein described, but to vary this, as well as the form of other parts, as I may deem proper, whilst I attain the same end by means substantially the same.

WM. RICHARDSON.

No. 4173.

What I claim as my invention, and desire to secure by letters patent, is combining a saddle, or other suitable seat and spring, with handles, the whole being mounted on a suitable frame, substantially in the manner described.

JAMES ELLIOTT.

No. 4174.

I am aware that slides have been applied to pen and pencil holders, for various purposes, as also projections to receive the ends of the writer's fingers, to protect them from the ink; and therefore I do not claim simply the application of spring slides or projections for the reception and protection of the fingers, as of my invention; but what I do claim therein as new, and desire to secure by letters patent, is the combining therewith a projecting piece, ring, or guard, which shall extend out from the holder sufficiently far to act as a guard in preventing the pen from passing too deep into the ink-holder, such ring or guard being attached to a spring sliding within the body of the pen-holder, to afford the ready means of strengthening the spring and for adjustment, substantially in the manner herein described.

It will be seen, that although the sliding part of my pen-holder bears some resemblance to the slide of a pencil-case and of some other instruments, its object and arrangement differ entirely from those of such slides, in its constituting a projecting guard, intended for a new and definite purpose.

DANIEL HARRINGTON.

No. 4175.

What I claim as my invention, and desire to secure by letters patent, is combining the two bolts by means of the dog or lever, so that when the inside bolt has been locked, the outside one cannot be locked, as described.

GEO. OATES.

No. 4176.

The improvements embraced in this new instrument, and for which I ask letters patent, are the method of combining the pieces of copper and zinc into an instrument, said pieces being insulated from each other, and having liberty to rock, so as to touch together, by being moved to the right or left, and thereby produce a galvanic shock: while they are so affected they

produce mechanical action—all as above described; by which a much greater (see above) number of shocks are experienced in a given time, than the ordinary instrument, in any of its forms, can be made to do, and thereby furnishing a large *increase* of curative or medicinal power. The above named improvements, it will be seen, are three-fold. There is also one other improvement embraced in this instrument, which is important to such invalids as are feeble in the strength of their fingers, which is a usual thing with emaciated females; the shocks produced by moving the turned-up end to the right or left can be accomplished with the least possible exertion of the hand, or thumb and finger.

It is my intention to vary the construction of the newly improved galvanic electric instrument, so as to adapt it to the requisitions of the various cavities of the human system, and the wants of invalids of all descriptions, still preserving and embracing its general principles, features, and improvements, as above described and claimed; and I do hereby declare that it is *not* my intention to claim anything *herein* that is embraced in my former letters patent.

DANIEL HARRINGTON.

No. 4177.

I do not claim as my invention the employment of a steam or other boat for assisting in saving or partially saving wrecks or other cargoes, as this has before been done; but what I do claim as my invention, and desire to secure by letters patent, is the employment of a caisson made of water-proof cloth, or other suitable material, rendered water-proof, or partly so, to enclose a wrecked vessel, for the purpose of excluding the surrounding water whilst pumping from the inside of the wreck and caisson, as herein described.

I also claim as my invention the employment of the movable frame or platform, in combination with the flexible caisson and wreck, for the purpose and in the manner described; and, finally, I claim connecting a pump, or pumps, with the caisson, and a steam engine or other first mover on board a boat, by means of the swinging crane, in combination with the universal joints, as herein described, to admit of the free movement of the boat or caisson, without affecting the connexions, as herein described.

PHINEAS BENNET.

No. 4178.

Having thus fully described the nature of my improvements in the manner of employing expanding bars or rods for preventing explosions and economizing fuel, what I claim as new therein, and desire to secure by letters patent, is the combining with a steam boiler of two such bars of brass or other suitable metal, arranged as herein described; said bars being also combined with each other, and with the apparatus by which the damper in the chimney is to be closed, and the draught through the furnace arrested, the same being effected substantially in the manner herein set forth. I do not intend, however, by this claim, to limit myself to the precise arrangement of the respective parts of my apparatus, as herein described, but to vary them as I may think proper, whilst I attain the same end by means substantially the same.

I do not claim the exclusive right to use expansion rods or bars to open or close valves or dampers, by variations of temperature, this principle for obtaining motion for such a purpose being well known; but I limit my claim to the foregoing improved arrangement and combination of parts for effecting this object.

JAS. MONTGOMERY.

No. 4179.

Having thus fully described the nature of my improvement in the manner of driving the bobbins, spindles, and flyers of a throstle, for the spinning of cotton or other fibrous substances, what I claim therein as new, and desire to secure by letters patent, is the giving motion to such bobbins, spindles, and flyers, by means of a horizontal friction-wheel, bevelled on its upper edge, so as to adapt it to the lower ends of the flanches of the bobbins, or some analogous device on the spindles, which are also duly bevelled; by which means I am enabled to give them the requisite motion, and to dispense with the use of bands for that purpose.

I do not claim to be the inventor of the method of communicating a revolving motion from one body to another, by means of friction, this having been frequently done in machinery of various kinds; but I do claim the manner of applying this principle to the driving of the bobbins or spindles of a throstle, or other similar spinning machine, under an arrangement of the respective parts, and for the purpose herein fully made known; by means of which arrangement and combination the use of bands is dispensed with, and the motion is more advantageously communicated than in the ordinary mode, whilst the revolving and traversing motions necessary to the winding up of the yarn upon the spools are given thereto.

BENJAMIN BRUNDRED.

No. 4180.

What I claim as my invention, (jointly with the late William Avery,) and which I desire to secure by letters patent, is the before described construction of the jaws for griping and raising the drill, in combination with the drill and winding ways for turning it, and the manner of closing the jaws by means of the aforesaid combination of the arm *u*, axle *c*, arm *g*, rod *h*, lever and cam, or any other combination substantially the same, for a similar purpose.

HIRAM H. SCOVILLE.

No. 4181.

Now I do not claim, as my invention, the application to purposes of propulsion of spiral blades, radiating from and fastened to a centre block or hub, letters patent for the same having been issued, in the United States, to Benjamin M. Smith, in 1829; but I claim as my invention, and desire to secure by letters patent, the hub, constructed with the perforated projections, and the combination of the same with the elliptic braces, for the purpose of sustaining and strengthening the spiral propeller blades, as herein before described.

J. ERICSSON.

No. 4182.

Having thus described the chief characteristics of my engine, the manner of constructing, arranging, and operating the parts, I wish it to be distinctly understood that I do not claim as my invention working the piston of a rotary engine in an annular groove or bent cylinder, nor do I claim admitting steam through a hollow shaft and passages made in the disk to which the piston is attached, nor elastic metal ring packing; but what I do claim, and desire to secure by letters patent, is—

1st. Making the annular or bent cylinder in two parts, divided by a plane parallel with the shaft of the engine, instead of at right-angles thereto, for the purpose and in the manner fully described.

2d. The arrangement of the elongated steam and exhaust passages in the disk to which the piston is attached, when combined with the arrangement of the valves and the periods of their motions, so as to cause them to establish an equilibrium (or nearly so) of the pressure above and below the valves, prior to and during their motions, substantially as described.

3d. The arrangement of the steam and exhaust passages in the disk in combination with the shifting valve governing the aperture in the tubular shaft, and the annular groove in the packing plate, for the purpose and in the manner described.

4th. Grooving the faces of the disk and packing plates, to admit steam to the rubbing surfaces, for the purpose of fabricating them, as described.

5th. Making the outer or rubbing surface of the piston of a single open-spring metallic hoop, in combination with the hempen or other packing within, and the mode of retaining the hoop by fitting it over the fillet projecting from the flanch that forms the connexion with the disk, which junction is rendered steam-tight by means of the inner packing, as described.

And, lastly, connecting the piston to a flanch projecting from the disk on the shaft, by means of screws passing through the enlarged apertures in the flanch, to admit of the free play of the piston, to adapt itself to the cylinder in case of inaccuracy, as described.

WILLIAM WRIGHT.

No. 4183.

Having thus described my invention, I shall claim the combination with the clay or mortar hopper, or reservoir, and one or both its chambers, discharging vents, or false moulds and pistons, of the reciprocating slide arranged within the hopper and upon its bottom, and operating to supply the end chambers and vents with mortar or clay, substantially as above described.

In testimony whereof, I have hereto set my signature this seventh day of June, A. D. 1845.

WILLIAM SANFORD.

No. 4184.

Having thus fully described the nature of my improvement in the manner of communicating heat to the ovens of cooking stoves, I do hereby declare that I do not claim any improvement in the general construction of stoves, my improvement in the lower oven flue being equally applicable

to stoves in a variety of forms; but what I do claim as my invention, and desire to secure by letters patent, is the forming of the bottom plate of the oven with a number of tubes or boxes, usually of sheet iron or other substance, thinner than the bottom plate, that descend from it through the lower flue space; the same being effected under an arrangement of their respective parts substantially the same with that herein described, and for the purpose set forth.

C. J. WOOLSON.

No. 4185.

Having thus described my improvement in "extension tables," I shall state my claim as follows: What I claim as my invention, and desire to have secured to me by letters patent, is the making or arranging either semicircular part of the top of said tables so as to be capable of a horizontal adjustment, substantially as herein above described, and for the purpose set forth.

In testimony that the foregoing is a true description of my said invention and improvement, I have hereto set my signature this twenty-ninth day of May, in the year eighteen hundred and forty-five.

CORNELIUS BRIGGS.

No. 4186.

What I claim as my invention, and desire to secure by letters patent, is the manner of connecting the right and left hand ploughs to the beam by means of the cap piece, the bolt, oblong opening, self-acting spring latch, and notches, all combined and operating substantially in the manner and for the purpose herein set forth.

I also claim the combination of the detaching cord, latch, spring, cap piece, and notches, arranged and operating substantially as herein set forth.

JOSEPH TRUMP.

No. 4187.

I do not claim as my invention simply griping the sheet of metal between the face of a stock and the bed, as this has heretofore been done; but what I do claim as my invention, and desire to secure by letters patent, is, first, making the folding plate to project from and on top of the stocks to which it is attached, or of which it makes part, arranged in combination with the bed of the machine and the folder, in the manner herein described, by means of which the edge of the sheet metal is griped and folded entirely over, substantially as herein described; and I also claim, in combination with this arrangement, the manner of preventing the folding-bed and folding plate from springing in the middle of the length, by means of the bolt, with its imbedded journal head, substantially as herein described.

HENRY A. ROE.

No. 4188.

What I claim as my invention, and desire to secure by letters patent, is the manner in which I have combined the coal fire chamber with the wood-fire chamber, by placing the grate of the coal chamber partly within the

top of the wood chamber, and in combination therewith the fluted form of the coal-fire chamber, to admit a draught from the wood fire to pass through the coal chamber, as herein fully expressed.

BENJAMIN T. RONEY.

No. 4189.

And having now described the nature of my said invention, and in what manner the same is to be performed, I declare that what I claim is, first, the application of ammoniacal salts, in the manner before described, to prevent and remove incrustration in the steam boilers and steam generators; and, secondly, the use of ammoniacal salts in *conjunction* with muriatic, acetic, or nitric acid, for the purpose of removing old incrustation, in the manner above described.

L. A. RITTERBANDT.

No. 4190.

What I claim as my invention, and which I desire to secure by letters patent, is the mode of regulating the speed of the mill by means of the fixed and movable rudders, roller, cord, and weight, in combination with the circular platform to which they are attached, containing the wind wheel and axle, and resting on friction rollers, in the manner set forth.

GEORGE PARKER.

No. 4191.

Having thus fully described the manner in which I construct my parlour grate, and arrange the respective parts thereof, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged the partitions and damper in the box, or heated air space, and combined them with the heated air tubes or flues, at each end of the grate, for the purpose set forth. I claim the forming of the jambs of the grate with open work offsets, in combination with the particular arrangements and provision made for setting the same, so as to constitute an air-heating chamber in the rear thereof, as described.

I do not make any claim to the forming of an air heated chamber at the back of a grate, but limit my claim to the particular manner, herein made known, of arranging the same, in connexion with the wall that receives the plate and the escape-pipe.

JAMES WILSON.

No. 4192.

What I claim as my invention, and desire to secure by letters patent, is the method of making the dyestuff or carasene from spent madder, by the chemical action of water, sulphuric acid, and an alkali, as described above.

FREDERICK PFANNER.

No. 4193.

I do not claim merely covering the wings of the propeller in such a manner that a section perpendicular to the shaft would produce a curved line,

nor do I claim making the wings approximating to the form of a conical surface; but what I do claim as my invention, and desire to secure by letters patent, is making the wings of the propeller in the precise form of such a portion of the convex surface of a regular cone as would be cut out by a plane or planes passing through its axis, and comprehending about half of its surface, each wing being attached along one of its straight edges, to the shaft.

L. PHLEGER.

No. 4194.

Having thus fully described the nature of our improved apparatus for enlarging or forming chambers within the openings made by boring the earth or rocks, what we claim therein as new, and desire to secure by letters patent, is the manner of constructing an instrument such as is herein described and represented, in which expanding cutters are so combined with a tubular shaft as that they may be received within it, and be made to open out by an arrangement of parts constructed for that purpose, and substantially in the manner herein set forth.

THOMAS S. SPEAKMAN.
RICHARD A. STRATTON.

No. 4195.

In conclusion, I claim the combination of the chisel carriage with a separate carriage, arranged to operate in the manner and for the purpose above specified.

Also, the combination of the slide cam on the chisel holder, arms, and straps; the whole being applied to the chisel holder, its carriage, and the carriage A, and operating substantially in the manner and for the purpose as hereinbefore described.

In testimony whereof, I have hereto set my signature, this twenty-third day of January, A. D. 1845.

CHARLES BENNET.

No. 4196.

I claim as my invention, and ask a patent for, a cotton gin brush, made of a cylindrical form, with holes or openings as above described, or made with pieces of lagging with open spaces between them, as above described; also, with openings at the ends about the axis of the shaft, as above described, and with heads, the outer ones having each a hoop, circular projection, or other equivalent contrivance, for cutting off currents and eddies of air, as above described.

I also claim as my invention, and ask a patent for, the hoop, circular projection, or other equivalent contrivance, at the head of the brush, for cutting off currents and eddies of air, as above described, with an opening within the hoop or circular projection for the admission of air, as above described.

EDWIN KEITH.

No. 4197.

What I claim as my invention, and desire to secure by letters patent, is

the arrangement of the dumb flues surrounding and within the oven, in the manner and for the purpose set forth.

PETER J. CLUTE.

No. 4198.

What I claim and desire to secure by letters patent, is, 1st, the *gate* and *agitator;* the bars of the latter working with freedom between the bars of the former in such a manner as to free the coal of ashes, so as to insure active combination.

2d. Also the arrangement of the collars, containing a number of holes in combination with the combustion cylinder and zigzag smoke pipes, for the purpose of preventing the too rapid escape of air into the apartment next above before it is sufficiently heated.

3d. Likewise the arrangement of plate B, in combination with the combustion cylinder and smoke pipes, as described.

4th. And also the arrangement of plate C, containing the register for regulating the draught through the coal, in combination with the register and smoke pipes and combustion cylinder.

H. L. B. LEWIS.

No. 4199.

What I claim as my invention, and desire to secure by letters patent, is connecting a crank pin with two cranks, by means of turning and sliding joints combined, whether the pin be made to slide in both cranks or only in one, so as to equalize the strain of the engine on each crank, and allow them to move and compensate for any error in the relative position of the crank shafts, as herein described.

FREDERICK ELSWORTH SICKELS.

No. 4200.

I do not claim to have invented any of the parts herein described and shown, except as follows:

I claim as new and of my own invention, and desire to secure by letters patent, the application of the movable hanging stile, hinged in a rebate in the doors or sash stile, and steadied in a groove in the jam by screws, either without or in combination with the springs H and K, and roller I, and inclusive of any variations arising from the nature of the particular case, when such application and combination, or variations, for the purposes herein described, are substantially the same in construction and practical effect, and shall be used in hanging or mounting French sashes, casement windows, or folding doors, of any description and for any purpose.

In witness whereof, I have hereunto set my hand in the city of New York, this sixth day of June, in the year one thousand eight hundred and forty-four.

AARON B. CARPENTER.

No. 4201.

What I claim as my invention, and desire to secure by letters patent, is

tripping the drop-valve of the cut off by a motion independent of the lifters, substantially in the manner and for the purpose herein described.

I also claim combining the wiper that drops the valve of the cut-off, whether working horizontally or vertically, with any of the moving parts of the engine other than the lifters, on their rocking shaft, by means of the sector and arm or arms, by means of which the extent of the cut off can be regulated at pleasure during the action of the engine from the full to the least portion of the stroke, as herein described.

FREDERICK ELSWORTH SICKELS.

No. 4202.

I do not claim letters patent simply for casting the steam chests with the cylinder, or with the cylinder bottom and condenser; but what I do claim as my invention, and desire to secure by letters patent, is casting the steam chests with the cylinder, or one with the cylinder and the other with the cylinder bottom and condenser, by making the side of the steam chest the side of the cylinder or condenser, in combination with the manner of fitting the cylinder head and the lower end of the cylinder to the chests, and the mode of making the attachments without the continuation of the flanches, thus dispensing with the nozles and nozle flanches, and their attachments, and saving at each stroke the steam contained in the nozles, all as herein described.

FREDERICK ELSWORTH SICKELS.

No. 4203.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is constructing the receiver, (figs. 3 and 4,) in the manner and for the purpose described, viz: by supporting its edges with springs, as set forth.

NELSON BARTLETT.

No. 4204.

What I claim as my invention, and desire to secure by letters patent, is giving to the spiral or twisted knife or cutter, attached to a flanch in a line radiating (or nearly so) from the axis of the stock, a traversing motion in the direction of its axis, in combination with a reciprocating rotary motion on its axis, when this latter motion is governed by the twisted plane of the cutter, or any thing essentially the same, to enable the grinder to give the required level to the ground face, and the proper line to the edge, substantially in the manner herein described.

WILLIAM HOVEY.

No. 4205.

What I claim as new, and as constituting my invention, and desire to secure by letters patent, is the forming or dividing of the upper part of the chimney into two or more curved and divergent branches or flues, with the inner walls of each formed in part or wholly of perforated sheet iron, upon the principle and for the purpose hereinbefore set forth.

I also claim the combination of the tubes or radial branches with the exterior case or jacket, forming as it does a chamber around and below them.

WM. C. GRIMES.

No. 4206.

What I claim as my invention, and desire to secure by letters patent, is, first, the combination of the griping bars, bent levers, and inclined planes, for griping the block for cutting the lath, as herein set forth.

Second, the combination of the "self-clearers" with the rest and knife, as herein described.

Third, the counting apparatus, constructed substantially as herein described, in combination with the lath-cutting machine.

SAMUEL CHENEY.

No. 4207.

What I claim as my invention, and desire to secure by letters patent, is the particular manner of constructing the dining-table to be heated with pure hot air, introduced by means of pipes from a furnace, as above described.

H. L. B. LEWIS.

No. 4208.

And, having thus fully explained the character of my invention, the essential modes of application, and the manner of making and using the same, what I claim as my invention, and as distinguished from all other things before known, is—first, making primers of fulminating mixtures, or such compounds as ignite by percussion in a continuous series, each primer, or any two or greater number, being separated from the others by a substance which is more or less combustible than the fulminating mixture, by which one or more may be exploded without communicating fire to the others.

Secondly, the mode herein described of moving and measuring out the primers, by the movement of the lock, substantially as described.

EDWARD MAYNARD.

No. 4209.

What I claim as my invention, and desire to secure by letters patent, is the before described construction of the knife; that is to say, making it with a series of sharp cutting edges, commencing near the top of the blade, on each side, and gradually downward and inward towards the centre, forming a serrated concave edge on both sides, each cutting edge being made in horizontal and parallel lines, the lower point being made sharp so as to pierce the article to be cut first, and each succeeding knife following in its turn and cutting the article.

GREY UTLEY.

No. 4210.

What I claim as my invention, and desire to secure by letters patent, is the confining the thin metallic reed, used in the above named instruments, to a sliding plate, and securing the said metallic reed and sliding plate in a case, so that the pitch of the reed may be raised or lowered by the turning of a screw attached to the sliding plate, substantially in the manner and for the purpose herein described and set forth.

CHAS. HORST.

No. 4211.

Having thus described my invention, I shall claim the above mode of guiding the saws, the same being effected by the curved slots of the pattern plates and blocks through which the saw works, in combination with vibrating arms applied to the saw frame and saw, as set forth, the whole being substantially as herein before explained.

In testimony whereof, I have hereto set my signature this second day of August, A. D. 1845.

FREDERICK W. HARRIS.

No. 4212.

What we claim as our invention, and desire to secure by letters patent, is the method above described, by turning the tongues or reeds of accordeons or seraphinas, and other instruments deriving their tones from the vibration of metallic reeds, by means of movable clamps, which gripe the reeds, and embrace a part of the plate to which the reeds are attached, and admit of sliding or moving to increase or decrease the length of the vibrating part of the reed, and thus regulate the tone, as herein described.

MARTIN SCHNEIDER.
NIKLAUS SCHNEIDER.

No. 4213.

What I claim as my invention, and desire to secure by letters patent, is the method of removing and putting in the driving and truck-wheels of locomotive and other railroad carriages, by the employment of a vertically moving platform for letting down and raising up the wheels, in combination with the permanent railway and trussel, or other support for the locomotive or car frame, substantially as herein described.

THOMAS D. SIMPSON.

No. 4214.

I do not claim simply the employment of a reverberator in a stove or fireplace, as this has heretofore been done, but for a different purpose and in a different manner; and, therefore, what I claim as my improvement, and desire to secure by letters patent, is the combination of a flange or "reverberator" with the hood or muzzle of a stove, under the eduction pipe or aperture, and projecting in front thereof, and inclining downwards,

whether of a greater or less width, or set at a greater or less angle, substantially in the manner and for the purpose set forth.

JAMES PEDDER.

No. 4215.

I do not claim as my invention making the warves of spindles, flyers, or tubes for carrying bobbins or spools, with flanches, nor the driving of them by a belt; nor do I claim driving spindles, flyers, bobbins, or spools, &c., by resting them on a belt, as all these devices and methods have been known and used before, but not as I have applied them; and, therefore, what I claim as my invention, and desire to secure by letters patent, is driving spindles, flyers, bobbins, or spools, &c., by means of a belt with parallel edges equal (or nearly so) in width to the space between the flanches of the warves, and passing between them when these warves are so arranged as to be suspended thereon, without the belt bearing against their peripheries, for the purpose and in the manner substantially as herein described.

WM. BAXTER.

No. 4216.

What I claim as my invention, and desire to secure by letters patent, is the combination of a sheaf box with the platform into which the grain is thrown before being deposited upon the ground from the platform.

FERDINAND WOODWARD.

No. 4217.

What I claim as my invention, and desire to secure by letters patent, is the arrangement of the series of tubes around the chimney, with their imperforated surfaces towards the centre of the chimney, to prevent the direct action of the exhaust, &c., from forcing the sparks through the perforations, as herein described.

I also claim the arrangement of the damper, or valve, with the inverted concave plate and cone at bottom, in combination with the series of tubes composed of perforated and imperforated surfaces.

I also claim, in combination with the series of tubes surrounding the chimney, the tubes attached to the outer casing, or the equivalents thereof, for conducting the sparks into the receptacle, that are carried by the force of the current up to the top, as herein described.

And, finally, I claim connecting the fire-chamber with the receptacle for the sparks, made in the lower part of the smoke-box, by a partition therein, by means of a lower tube or range of tubes corresponding with the flue-tubes, so as to carry back the sparks to the fire chamber by an arrangement entirely within the casing of the boiler and furnace, and acted upon by the current, as herein described.

WILLIAM DUFF.

No. 4218.

What I claim as my invention, and desire to secure by letters patent, is—

1st. The combination of the slide-rest, guided in the manner set forth,

with the tool for turning off the cask, constructed and arranged in the manner set forth.

2d. I also claim the apparatus for chamfering, and howelling, and crozing; that is to say, the combination of the cylinder, open at both ends, so that both ends of the cask can be worked off without changing—with the chucks for fastening the cask into the cylinder, and with the tools, as herein described, for chamfering and howelling.

3d. I also claim the crozing-tool, with the changeable face-plate, as herein set forth.

4th. I likewise claim the combination of the stock, cutter, adjustable and gauge-plate, constituting the tool for turning and smoothing the outside of the cask, as above described, and represented in fig. 4.

5th. I likewise claim the peculiar construction of the tool for howelling the cask, as above described, and represented in fig. 9.

6th. I likewise claim the peculiar construction of the tool for chamfering the ends of the cask, as above described, and represented in fig. 8.

WM. TRAPP, Jr.

No. 4219.

What I claim as my invention, and desire to secure by letters patent, is the combination of a series of pairs of cylinders, each pair having spiral-formed slats or bars on them, the slats in each pair running in contrary directions from that immediately preceding, so as to break the hemp in several directions, as herein set forth.

I also claim, in combination with the dressing-cylinder or cylinders, the vibrating motion of the feeding rollers, so as to draw the hemp in and out again, as before described.

BENJAMIN M. SMITH.

No. 4220.

What I claim as my invention, and desire to secure by letters patent, is moulding or casting the socket on a screw-former, which can be withdrawn from the glass after it has solidified, and before it contracts sufficiently, by cooling, to split or crack, as described.

GEO. O. RUSSELL.

No. 4221.

What I claim as my invention in the above described improvement, and desire to secure by letters patent, is the application of an air-inclined valve or clapper, having a surface of glass or other hard, smooth material, in combination with said inclined valve and ink-tube; which valve is forced upwards by means of springs, or otherwise, upon the bottom of the ink-tube, and arranged substantially in the manner and for the purposes above set forth and described.

WALTER HUNT.

New York, *September*, 1845.

No. 4222.

What we claim as our invention and improvement, and desire to secure by letters patent, is the combination of the adjustable wheel with the adjustable beam, as described.

THOMAS B. QUIGLEY.
HARVEY HALL.

No. 4223.

What I claim as new, and for which I ask letters patent, is the causing the pens to be raised by the edge of the paper, in its passage through the machine, thus causing each sheet to determine the length of its own lines.

LEWIS EDWARDS.

No. 4224.

Having thus fully described the nature of my improvement in the process of manufacturing the salts of chrome, what I claim therein as new, and desire to secure by letters patent, is the using of wood ashes in mixture with the chrome ore, and with the alkaline salt, for the purpose and in the manner herein fully set forth.

ISAAC TYSON, Jr.

No. 4225.

Having thus fully described my invention, I wish it to be understood that I do not claim an endless platform, formed of sections; nor do I claim the manner of moving them, they having been before used for a horse-power; but what I do claim as my improvement, and desire to secure by letters patent, is the endless sectional platform or carriage, such as herein described, which forms the bed for planing on in combination with the rotating cutters, in the manner and for the purpose set forth, whether the central bar be used or not; and I also claim the sectional platform or carriage in combination with the central bar, for the purpose and in the manner described.

BENJAMIN BROWN.

No. 4226.

I do not claim as my invention the employment of a series of rollers connected by rings at each end around the axle, and within a box, as this has long since been done; but what I do claim as my invention, and desire to secure by letters patent, is making the ends of such rollers on a bevel or mitre, in combination with shoulders, collars, flanches, rings, or other projections on the axle, and on the box or hub, having corresponding bevels or mitres to avoid the rubbing friction at the ends of the rollers, and the more effectually to prevent end play, substantially as herein described.

WILLIAM ROWAN.

No. 4227.

My invention or improvement, and therefore that which I claim, consists in the employment of the perforated plate in combination with the cutting cylinder and feed cutters; the whole being arranged and operating substantially as set forth.

In testimony whereof, I have hereto set my signature this second day of April, A. D. 1845.

JOSEPH S. L. HUNT.

No. 4228.

What I claim as my invention, and desire to secure by letters patent, is the combination of the handle (fig. 1) and the cylinder, (fig. 2,) part of each of which being removed, in the manner and of the shape described in the above specification, for the purpose of receiving the slip of pegs, and to be held therein and conveniently to be advanced, *by means of the thumb of the hand holding the implement*, towards the chisel, (fig. 1 and fig. 2,) which successively splits off the single pegs from the slip, (fig. 1;) said handle and cylinder being constructed either of one entire piece of suitable metal; or, to render the implement less weighty, part of the handle may be made of wood, in the manner fully described above, which latter mode of construction is considered preferable.

JOHN C. BRIGGS.

No. 4229.

I am fully aware that there is nothing new in the employment of a lever and a connecting bar for the purpose of withdrawing or retracing, or otherwise giving motion to an article of mechanism, and therefore I do not lay claim to such; but that which I do lay claim, is the combination of a screw pin with the connecting bar, in such manner as to be applicable to the shank of the knobs, or detachable therefrom, as herein described.

In testimony whereof, I have hereto set my signature this tenth day of September, A. D. 1845.

JOHN CLEVELAND PALMER.

No. 4230.

I shall therefore claim the peculiar manner in which the grate bars are made, so as to operate in connexion with the cylinders, viz: triangular in cross section, so as to present an acute angular or sharp edge for the teeth of the cylinders to act against, in order to remove the bur or burs, as described.

I also claim a toothed fan and grate, in combination with the main and picker cylinders F and G, and grate H, the whole being arranged and used, in connexion with a feeding apparatus, substantially as above described.

In testimony whereof, I have hereto set my signature this second day of July, A. D. 1845.

THOMAS S. WASHBURN.

No. 4231.

Having thus fully described the nature of my improvement in the manner of constructing the fine comb cylinder of a machine for the burring and cleaning of wool or cotton, what I claim therein as new, and desire to secure by letters patent, is the constructing of said cylinder by covering its periphery with metallic plates of such width as may be desired, and extending from end to end thereof, on which plates grooves or channels are to be cut, and the teeth to be formed on one of their edges, in the manner and for the purpose herein fully made known.

ALANSON CRANE.

No. 4232.

What I claim as my invention, and which I desire to secure by letters patent, is replacing cars that have run off the track, by drawing them up logitudinal inclined planes, formed on blocks of any suitable material, connected together and placed in front of the several wheels, and thence on the transverse inclined planes formed on said blocks, immediately in front of said longitudinal planes, and terminating on a level with the rails, down which said wheels are caused to slide, by the gravity of the car, to their proper positions on the track, as set forth.

SAM. H. BEAN.

No. 4233.

What I claim as my invention, and desire to secure by letters patent, is connecting railroad cars, locomotives, &c. by a link provided with a segment of a circular flanch or flanches, embraced in the manner herein described, which will be liberated when the bodies, thus connected, deviate sufficiently from the line of the road, substantially as described, in combination with a spring joint, as herein described, to facilitate the liberation of the link when the car, &c. leaves the track, by a motion upward or downward, as well as horizontal, as set forth.

RICHARD HEMMING.

No. 4234.

What I claim as my invention, and desire to secure by letters patent, is connecting the carriage with the slides (or slide) that operate it, at some points between the middle of its lengths and the ends of the block, so that at each vibration one end shall be moved forward and the other back, as herein described, to form the shingles with that part towards the butt with parallel faces, as specified.

I also claim operating the two sliding blocks that carry the carriage by means of a groove, formed as herein described, in the surface of one cylinder, so that one of the slides shall remain still whilst the other is moved forward, as described. And, finally, I claim connecting the rod that moves one end of the carriage, with its appropriate slitting block, by means of a slide, governed by an adjustable screw or other analogous device, for the purpose of adjusting the face of the block or bolt of wood to the knife for the cutting of the first shingle, as described.

A. S. PELTON.

No. 4235.

Having thus fully described the nature and operation of my improved machinery for manufacturing forks and other articles of a like character, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have combined and arranged the respective parts of the machinery for cutting, filing, or dressing the handles, as herein described; that is to say, I claim the manner of arranging and combining the revolving cutters or files, the pattern by which the form to be given to the handle is governed, the rocking frames which carry the cutters, and the sliding frame, being made to co-operate in their action substantially as set forth.

In that for dressing the prongs, I claim the combination of the revolving wheels with their cutters, and with the rests which pass in between said wheels, for the purpose and substantially in the manner herein made known.

SAMUEL H. GILMAN.

No. 4236.

I do not claim two series of sliding plates or tumblers, arranged side by side, and the one series having recesses in each plate, and the other series having corresponding projections to enter and move in the said recesses, and the one series being affixed to the main bolt, so as to move back and forth, as well as up and down with it, and having a corresponding series of notches or indents in each of its plates, and one spring catch applied to or affixed upon the main bolt, which spring is thrown, by a suitable projection, from the lock case into one of the notches of each of the several plates whenever the bolt is shot forward by the key, and out of the same, by a similar contrivance, when the bolt is retracted, (the projections of the front series of plates being carried so far forward, or out of the recesses of the rear series, when the bolt is thrown forward or locked, as to permit of the fall or vertical depression of each of the plates of the rear series of plates,) all of which will be found to exist in certain locks heretofore patented or sold; but that which I do claim is my specific improvement thereon, the same consisting in the combination with the main bolt and two series of sliding tumblers, constructed and acting together, as above set forth, of a solid stud, (projecting from the bolt;) the slots (cut as above described in the tumblers of the front series) and a vibrating or moving plate applied to the main bolt and rear series of tumblers, as specified, the whole being arranged and operating together substantially as herein before explained.

In testimony whereof, I have hereto set my signature this ninth day of October, A. D. 1845.

WM. HALL.

No. 4237.

What I claim as my invention, and desire to secure by letters patent, is the lower part, or second mill, which receives the bark from the upper and discharges it through the side or bottom of the mill, or both, by the aid of arms or flanges attached to the nub or shaft, which force the bark through grater or double-saw teeth, whichever are used.

ISAIAH SCUDDER.

No. 4238.

Having thus fully described the manner in which I now construct my rotary top stove, what I claim as new therein, and desire to secure by letters patent, is the combining with a stove furnished with a rotary top an oven occupying the whole area of the lower part of the stove, and furnished with flues, arranged and governed in the manner herein set forth. I do not claim either the manner of forming the oven, or of arranging the flues, as in itself new; but I claim them only in their combination with the rotary top stove, by which that stove is rendered much more convenient and efficient than under any former construction thereof.

HENRY STANLEY.

No. 4239.

Having now described the nature of our "improvements in producing and multiplying copies of designs, and impressions of printed or written surfaces," we would have it understood that we do not confine ourselves to the details shown and described, provided the peculiar character of the arrangements or processes be retained. We would also have it understood that we make no claim to many of the separate parts herein described, but what we claim is—

1st. The herein described process, whereby we transfer by means of treating the originals with acids of strengths varying with the induration of the ink, and so pressing out the acid as to cause an etching of the blank spaces, and a reversed impression of the original (where protected from the action of the acid) on metallic surfaces.

2d. The process of reviving the printing ink on originals, by first acting on them with caustic potash on its carbonic and tartaric acid, so as to form cream of tartar in the paper, which prevents the adherence of fresh ink in the blank spaces, while the old ink is left in a state to take up an additional quantity from a roller passed over it.

3d. The herein described process of preventing the adhesion or sticking of printing ink, during the operation of printing, to any part of the plates which are required to remain blank, by acting upon such blank surfaces with acid preparations of phosphorus.

In witness whereof, we, the said C. F. Baldamus and F. W. Siemens, have hereto set our hands and seals this thirteenth day of January, one thousand eight hundred and forty-five.

CARL FREDERICK BALDAMUS.
F. W. SIEMENS.

No. 4240.

I do not claim to have invented "blow-up" or heater, herein described, or any portion of the filtering pipes, cocks, or valves, that most immediately and properly belong to that vessel, as the whole thereof are already well known; but I do claim as new and of my invention—

1st. The application of the intermediate cylinder or vessel, with the connecting pipe, (*i*) steam pipe, and steam cock, for admitting steam, to press on the article under treatment when applied in combination with the buoy float, chain, supply valve, and steam valve, for the purpose of maintaining

a regular and successive supply of liquor and pressure of steam thereon within the vessel, for the purposes set forth, and substantially as described and shown.

2d. The application of the exit pipes and nozles to the filter boxes, to receive and act in combination with the thimbles of the filter leaves or frames, including any merely mechanical variation in the construction of the parts that shall be substantially the same in the means employed and the effects produced.

3d. The mode described of constructing the filter leaves or frames, which may be of wood alone, or of wood and metal conjointly: in either case each framed together in a tapered form, to allow of the bags being drawn tightly on, and easily drawn off, for cleaning, and the combination therewith of the groove and thimbles in the lower frame piece, when such mode of construction and combination, or any variations substantially the same, are used for any of the purposes herein set forth.

4th. The application of tapered filter bags to envelope the frames when used in combination with the means of securing the same on the frames by the tightening rod, (1,) and staple clasp, (2,) for the purposes set forth and substantially as described and shown.

In witness whereof, I, the said Ethan Campbell, have hereunto set my hand, in the city of New York, this fifth day of April, in the year one thousand eight hundred and forty-five.

ETHAN CAMPBELL.

No. 4241.

Furthermore, I claim as my invention the adaptation of the above described shutters in said board that prevents the sound from escaping only at the pleasure of the player on the piano forte; I also claim as my invention the above described arrangement of the shutters as connected with the pedal, to give the motion of the shutters by the use of the pedal; I claim, also, as my invention, the combining the swell with the piano forte by means of a covering over the strings, and having shutters in said covering, as above described, so as to confine the sound; and, with the use of the pedal, as above described, the shutters in said board are made to open and shut, gradual or quick, at the pleasure of the player, and can produce the crescendo and diminuendo tones, or swell in the piano forte, as above described; and, by opening and shutting the shutters quick, the player can produce the explosive and pressure tones by the above described mode, by the use of the pedal.

EDWARD BADLAM.

No. 4242.

What I claim as my improvement or invention, and desire to secure by letters patent, is the combination of materials and proportions, as embraced in this application, for making into various articles that the composition will admit of, by moulding, twining or pressing, burning, and glazing, which is a great improvement for some articles over clay, in use of ochre.

JOEL FARNAM.

No. 4243.

What I claim as my invention, and desire to secure by letters patent, is the combination of the hook and key, constructed in the manner set forth, crossing each other, and thereby forming a double inclined plane, so that by turning the key they are locked and the joints drawn tight, as herein described.

IRA SMITH.

No. 4244.

What I claim as my invention, and desire to secure by letters patent, is the combination of the two sets of knives for slitting and cutting off, with the bevel guiding rims for crushing and grinding fodder and other substances, as herein described.

JESSE URMEY.

No. 4245.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is the shank of the tooth, so formed of thin metal as to receive a wedge in its recess, in the manner described, for the purpose of firmly connecting it with the beam in all directions, as set forth.

DAVID B. ROGERS.

No. 4246.

Having thus fully described the nature of my improved hat, which is principally intended for the use of watchmen and firemen, I do hereby declare that I do not claim to have invented anything new in the manner of forming such hats, but what I do claim as new, and desire to secure by letters patent, is the manner herein described of forming or combining of welts or ribs with hats having bodies of wool, as represented at AA, in the accompanying drawing; such ribs being strengthened by filling the inside of the same with any suitable material, in the manner set forth, by which combination I form a hat, as hereinbefore stated, of a material not hitherto considered as applicable thereto, and possessing the desirable properties of lightness, and of being brought into market at a cost far below those that have been heretofore made.

JAMES BROWN.

No. 4247.

What I do claim, however, is the combination of the feeder, as described, with the bulged form of the back. I further claim the drawing in the upper segment of the back, over the coal, in combination with the shelf above the grate, and this I do claim without reference to the bulging of the lower segment.

JORDAN L. MOTT.

No. 4248.

What I claim is the *combination*, as follows: The top range or stove, furnished with both *rotary boiler plates* and *stationary* boiler *openings*, in combination with the *divided draught*, by which the *heat* can be made to act either on the rotary plate or the stationary boilers, or both, at pleasure, by merely changing the dampers.

JORDAN L. MOTT.

No. 4249.

And, therefore, what I claim as my invention, and desire to secure by letters patent, is the series of eccentric or regular saw plates on the cylinder, in combination with the comb, for the purpose of cutting corn in the ear, or other substance, substantially as herein described, and in combination therewith. I also claim the conical mill for grinding the grain, &c., after being cut, substantially as herein described.

J. P. ROSS.

No. 4250.

Having thus fully described the construction and operation of my labor saving cart, what I claim therein as new, and desire to secure by letters patent, is—

1st. The combination of the shaft, crank, pinion, spur wheel, ratchet, pulleys, and straps, and elevated cross piece, arranged and operating substantially in the manner and for the purpose herein set forth.

2d. I also claim the combination of the tail board, balance levers, straps, and cross piece, arranged and operating substantially in the manner and for the purpose herein set forth.

3d. I also claim the combination of the bolt, spring V, spring catch W, upon the tail board, and metallic plate, upon the axle, arranged and operating substantially in the manner and for the purpose herein set forth.

THOMAS MUSSEY.

No. 4251.

What I claim as my invention, and which I desire to secure by letters patent, is the combination of the strap, metallic plates, or bars, connected by a cross bar, and suspended on pivots, levers, and nicked plate, as set forth, for securing of the machine to the timber to be bored, said strap being hooked to the lever and passed under the timber, around the rollers, and between the bar and the side of the box, as described.

A. WEIKART.

No. 4252.

What I claim as my invention, and which I desire to secure by letters patent, is combining the internal escritoir with the external folding desk, in the manner and for the purpose set forth.

JOHN WHITE.

No. 4253.

Having thus fully described my apparatus for tanning hides, what I claim as my invention, and desire to secure by letters patent, is the combination of a traversing carriage for distributing the ooze on the hides, substantially as above described, with a vat or vats, in which said hides are suspended, and from which the spent liquor can drain.

FRANS. D. PARMELE.

No. 4254.

Having thus fully described the construction and operation of my improvement, what I claim as new therein, and desire to secure by letters patent, is the useful combination of the brake or rubber with a shaft or shafts, jointed to the goosenecks by a rule joint, in the manner and for the purpose herein set forth and fully made known.

WILLIAM DUNNING.

No. 4255.

What we claim as our invention, and desire to secure by letters patent, is the construction of a fracture apparatus with four adjustable side-splints, connected with each other by means of circular metallic hoops or bands, the upper and lower sets of splints being connected by means of the quadrant hinge joint and the ankle joint, similarly constructed. We do not claim these parts separately, but in combination, as above described.

WM. MILLS.
MAHLON HOAR.

No. 4256.

What I claim as new, and desire to secure by letters patent, is the arrangement of the draught in combination with the stoke flue, by which the smoke flue becomes the stoke flue, in the manner described.

RUSSEL WILDMAN.

No. 4257.

I am aware that the washing machine, the keir for boiling, first in lime and then in an alkali, the "chemics" or vats for containing the chlorine, and the "sours" or vats for containing the acid solutions, have all heretofore been used separately, the pieces of fabric being attached together to introduce them to the washing machine, and then separated to transport them by hand to the keir, and then retransported and re-attached, to rewash them, and the same with reference to the chemics, and sours, and the washer, the whole of these operations of attaching, detaching, conveying, and reconveying being done by hand; and therefore I wish it to be distincly understood that I do not claim as my invention the using of those in succession in the process of bleaching, nor do I claim the passing of wet fabrics from a tub or vat, between rollers, to force out the liquid, as this combination has heretofore been known and used; but what I do claim as my invention, and desire to secure by letters patent, is combining the wash-

ing machine with the keir, by means of carrying rollers or belts, provided with a reversed motion, so that the fabrics can be conveyed from the washer to the keir, and back from the kier to the washer, as herein described.

I also claim combining the washer with the several chemics or vats for containing chlorine, &c., in the manner described, so that the fabric may be conveyed from the washer to the chemics and the squeezing rollers, as herein described, and, in combination with this last combination, the arrangement of the "sours" or vats for containing the acid solution, and the set of squeeze rollers which receive the fabrics from the sours after they have been conveyed therein from the first set of squeeze rollers, and reconveying them to the washer, as herein described.

And, finally, I claim combining together the washing machine, the keir, and the chemics, the first set of squeeze rollers, the sours and the second set of squeeze rollers, in the manner described, by means of which the various operations in the process of bleaching are connected together, so as to convey and reconvey the fabrics from the one to the other in the order required, substantially as herein described.

MOSES PIERCE.

No. 4258.

Having thus fully described the nature of my improved ink holder, and shown the operation thereof, what I claim therein as new is making the rotary top of the ink holder, with pen holes, and a cup-formed recess in the middle, fitting in a large central opening in the permanent top, which is also provided with pen holes, in like manner, as the rotating top; when the two are combined by means of the spring handle, which secures the two together, and affords an easy and ready mode of removing the top to supply ink, whilst it answers the purpose of a ball handle, to carry the ink holder.

And I do hereby declare that I do not intend to limit myself to the particular form of the respective parts, as herein set forth and represented, but to vary these as I may think proper, whilst the general form and combination are substantially the same with those herein fully made known.

DANIEL HARRINGTON.

No. 4259.

Having thus described my invention, I shall claim the above described peculiar manner in which I arrange the cylinder with respect to one or two melting cisterns, and the furnace whereby the said cylinder is heated wholly or partially by the fire of the furnace, and receives its supply of lead, as above specified.

I also claim the combination of the air chamber with the forcing cylinder, and the pipe former, in the manner and for the purpose or objects as above specified.

I also claim the arrangement of the air chamber within, or partially within, the melting cistern or cisterns, for the purpose of melting any lead which at any time may congeal, or may have congealed, within the said air chamber, the said lead being rendered fluid by means of heat proceeding from the molten lead of the kettles, and passing through the sides (or a portion thereof) of the air chamber.

In testimony whereof, I have hereto set my signature this nineteenth day of July, A. D. 1845.

NATHAN BUTTRICK, Jr.

No. 4260.

We claim the method, herein described, of forming the oven bottom, and uniting it with the flue division plates, by the bent or curved edges of the plates forming the oven bottom, and fitting against the division plates of the flues in such manner as to receive a current to render the joints air-tight, substantially as herein described.

JOHN B. CHOLLAR.
EBER JONES.
PETER LOW.

No. 4261.

What we claim as our invention, and desire to secure by letters patent, is "the combination of the forceps handles, with the manner of controlling the hook, substantially in the manner and for the purpose described."

JOHN W. BAKER.
WILLIAM WILLSHIRE RILEY.

No. 4262.

What I claim as my invention, and desire to secure by letters patent, is the combination of the mallets and spring-hooks with the treadles for operating the mortising tools; that is to say, I claim attaching spring-hooks, having their lower ends tapered, to the sides of the sliding mallets, which, on the descent of the said mallets, come in contact with stops or cams on the frame, by which the direction of the hooks is changed inward, causing the hook to pass under the head of the cutting tool simultaneously with the descent of the mallet, so that when the mallet is again raised with the hook, it draws up with it the cutting tool to the desired height, when the hook, by its tapered form and effort to assume its original position, recedes from the cutting tool, until it is entirely liberated from it.

ALMON DOWNS.

No. 4263.

Figure 1 represents a plough when completed, the beam and handles of which are made of wood, and are in the usual form. I make no claim to securing the parts by a single bolt; but what I do claim as my invention, and desire to secure by letters patent, is the combination of the point, cutter, and mould-board, by means of the mortises in the point and the cutter, the tenon on the lower edge of the cutter, and the dovetail tenon on the land side of the mould-board, so as to unite them and render them more permanent and durable than ploughs now in use.

JOHN BALL.

No. 4264.

Having thus fully described my improvement, I wish it to be understood that I do not claim as my invention the close cylinder, having projections

thereon, nor do I claim constructing the concave with projections from its inner surface; but what I do claim as my invention, and desire to secure by letters patent, is the combination of a *close* cylinder, not admitting air at the ends, constructed, as above set forth, with a concave, having vertical projections thereon between the rows of holes in the said concave, in the manner and for the purposes herein described, and in contradistinction to an *open* cylinder, with said projections combined.

I also claim the fan, constructed in the manner described, with inclined heads to the case, for the purpose described, in combination with the smut machine; all arranged as herein set forth.

JOSEPH JOHNSON.

No. 4265.

Having thus fully described my improvement, what I claim therein as new, and desire to secure by letters patent, is the combination of the cutter or shears, projecting down in the centre, so as to commence cutting in the middle of the plate, with the die forming the teeth of the cultivator, substantially in the manner and for the purposes set forth.

DAVID B. ROGERS.

No. 4266.

Having thus fully described the nature of my improvements in the illuminating vault cover, what I claim therein as new, and desire to secure by letters patent, is the combining with the covering plate a series of glasses of any suitable form, or of lenses such as are shown at AA; said combination being effected substantially in the manner described, by the aid of laminæ of wood, or of soft metal, as shown at CC, and the glasses or lenses being defended from injury by knobs, or protuberances, as herein set forth.

THADDEUS HYATT.

4267.

What we claim as our invention, and desire to secure by letters patent, is—

1st. The combination of the reel with the hinged carriage for holding and turning the staves, to be planed, as described.

2d. We also claim the combination of the apparatus for crozing, chamfering, and cutting the staves to the required lengths, as herein described, to wit: the lever, with its holding arms, the holding beds, the swinging arms, cutters, and discharging springs, arranged and operated substantially as set forth.

3d. We likewise claim the arrangement of the circular saws on the inclined sliding shafts, for jointing the staves to the required bevel, in combination with the inclined planes or arms for rendering the apparatus self-acting, as described.

JOHN MINER.
SILAS MERRICK.

4268.

As all the parts herein described and shown, taken separately, have been

used before, for various purposes, I do not claim to have invented any of such parts, but I do claim as new, and of my own invention, and desire to secure by letters patent,

1st. The mode described of giving any required angle or bevel to the shoulders of tenons, by the operation of the bearer and screw, in combination with the means of fixing the length between the tenon shoulders by the slide stop-spring and set screw, as they are described herein.

2d. The model of mounting the tenon planes on frames in cross-slides on the carriage, in combination with the means of adjusting the depth of each tenon, by gauge screws, slide and catch 7, and set screw 8, and the further combination with these parts of the springs to force the planes towards the centre of the machine, in the act of cutting the tenon, substantially as is herein described.

In witness whereof, I have hereto set my hand, in the city of New York, this sixth day of July, one thousand eight hundred and forty four, in the presence of the witnesses subscribing hereto.

JAMES BIGGS.

No. 4269.

Having thus fully described our improvements, what we claim as new, and desire to secure by letters patent, is the combination of the variable fire-chamber with the boiler, constructed and arranged as described.

R. PECK.
JAMES W. COCHRAN.

No. 4270.

I do not claim the series of notched circular plates, &c., simply; but that which I do claim is the combination of the geared change wheels or plates CC, &c., with the said notched plates applied to them, and acting in connexion with them, and operated by an arbor and tooth, or cam, or other mechanical equivalents, substantially in the manner as above described.

I also claim the combination of mechanism by which the tongues or projections of the latch are kept from contact with their respective circular notched plates, when the main bolt is locked or thrown forward, the said combination consisting of the balance or fly-wheel, chain, and spring, or other mechanical equivalents, the slide-plate, lever, (connected to the slide H,) and the slide *u*, the whole being arranged and operated by the arbor and its tooth, substantially as above set forth.

In testimony whereof, I have hereto set my signature, this first day of November, A. D. 1845.

HENRY ISHAM.

No. 4271.

Having pointed out the principle of my invention, and the manner of constructing and using the same, and indicated some of the variations in construction, which may be made without changing the principle or character which distinguishes it from all other things before known, what I claim as my invention, and desire to secure by letters patent, is communicating the motions to the pen or pencil by means of cams acting on frames,

so that the vertical and horizontal strokes can be given by separate movements, and the oblique and curved strokes by the combined action of the two, substantially as herein described.

And I also claim giving to the sheet of paper, or other substance to be written upon, a horizontal movement for spacing off the letters, and a vertical movement for the lines, in combination with the movements of the pen or pencil, substantially as herein described.

CHARLES THURBER.

No. 4272.

Having thus fully described my improvements, what I claim therein as new, and which I desire to secure by letters patent, is the combination of tubes, as subscribed on the inclined planes, with the double shell of the drawer, in the manner and for the purposes set forth.

CHRISTOPHER SUYDAM.

No. 4273.

Having thus fully described the manner in which I construct my portable forge, and arrange the respective parts thereof, what I claim therein as new, and desire to secure by letters patent, is the combination of the curved sliding-shutters for enclosing the space over the fire, and the device for admitting a draught of air to keep up the combustion during the intervals in which the bellows are not employed; the same being effected for the purpose and substantially in the manner made known.

CHRISTIAN V. QUEEN.

No. 4274.

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of the fire-chamber and roasting-oven, having doors opening into the fire-chamber when direct radial heat is required in the oven.

I also claim the combination of the boiling apartment and baking-oven, constructed in the manner set forth.

JOHN PORTER.

No. 4275.

Having thus fully described the nature of my improvement in the manner of forming hat bodies of wool, fur, or other suitable material, what I claim as new therein, and desire to secure by letters patent, is the manner herein set forth of saving the labor of reblocking and of ironing such bodies, by interposing between them and the block a material to which resinous stiffening will not adhere, or to which, if it adheres, said material will not adhere to the block; by which device, in either case, the body may be allowed to dry upon the block, and may be removed therefrom in perfect form.

MARMADUKE OSBORNE.

No. 4276.

What I claim as my invention, and desire to secure by letters patent, is the mode, herein described, of hanging the car body, and governing its lateral motion; that is to say, the spring-bolster constructed and governed in its motions substantially as herein described, in combination with the springs and shackles; the whole being constructed and operating substantially as herein set forth.

LEVI B. THYNG.

No. 4277.

We claim the combination with a cam, or other mechanical equivalent of mechanism, substantially as set forth, for laying a sliver therein in eccentric helices, as above described; also the combination with the above of a corresponding frame or plate, disposed over it and operating so as to condense the material, or force it into the cam, as above specified.

In testimony that the foregoing is a correct specification of our said invention, we have hereunto set our signatures, this second day of August, in the year of our Lord eighteen hundred and forty five.

JOHN TATHAM.
DAVID CHEETHAM.

No. 4278.

What I claim as my invention, and desire to secure by letters patent, is the method, herein described, of uniting the various parts in making shirred or corrugated India rubber fabrics, by passing the cloth and strips of India rubber between pressure-rollers, one or both of which is grooved in the manner described to receive the strips of India rubber, and make pressure on cloth between the strips, as herein described.

And I also claim connecting the driving feed roller with the gearing which drives it, by means of a ratchet, to admit of turning it back to stretch the strips of India rubber, when this is combined with pressure rollers, the peripheries of which move with greater velocity than that of the feed rollers, as herein described.

JAMES BOGARDUS.

No. 4279.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by letters patent, is, first, forming a recess in the breast of a chimney, over the arch of the fireplace, for the reception of external air, and delivering the same in a thin stratum, as herein described, the whole width of the arch, in the manner and for the purposes above set forth.

I also claim gathering the throat of the flue, as above described, by curving out from the side that the flue is to be carried up on, and curving the other side up over it, as above specified.

JOHN PLANT.

No. 4280.

I am aware that a series of cutters, or disks, have been secured on a shaft by means of a nut, and therefore I wish to be distinctly understood that I do not claim this as my invention; but what I do claim as my invention, and desire to secure by letters patent, is the method herein described of adjusting the cutter edges of two series of cutting wheels, which fit between each other, by having each series to slide endwise on a shaft, so that the edges of the two series can be forced into contact by a nut, wedge, spring, or other analogous device, as herein described.

JAMES BOGARDUS.

No. 4281.

What I claim as my invention, and desire to secure by letters patent, is extending the tube below the traverse rail, in the manner and for the purpose set forth.

ALEXANDER ANDERSON.

No. 4282.

What I claim as my invention, and desire to secure by letters patent, is the introduction of the arch in the middle of the bottom, whereby I am enabled to obtain great power of resisting the strain caused by the tension of the wire strings of the piano forte, besides other advantages in improving the qualities of the instrument by keeping the case always in shape, so that it cannot draw up or "wind," as is invariably the result in the present mode of manufacture, and consequently keeping the instrument in tune and order for a much longer period.

Witnessed the sixth day of September, in the year of our Lord one thousand eight hundred and forty-five.

WILLIAM F. SENIOR.

No. 4283.

Having thus fully described the manner in which I construct my planing and jointing machine, and shown how the respective parts thereof operate, what I claim therein as new, and desire to secure by letters patent, is the manner herein set forth of forming, arranging, and combining with the revolving cutter wheel, the revolving platform, and the endless aprons between which the board to be planed is to be passed; by means of which arrangement and combination it is firmly held along the whole length of such apron, and carried regularly forward, without deviation.

JOSEPH E. ANDREWS.

No. 4284.

What I claim, and desire to secure by letters patent, are the flue passages across the top of the stove for the fire and heated air, after the same have been made to pass round the oven, and up to the top of the flue in front of the fireplace, to be continued to the stove pipe, as above described.

ELI C. ROBINSON.

No. 4285.

What I claim as my invention, and desire to secure by letters patent, is combining the elevating screws with the frame of the propeller, by means of openings therein to receive the same, so constructed as entirely to exclude the surrounding water from that part of the screws which is within the frame, the whole being constructed and arranged substantially as herein set forth.

R. F. LOPER.

No. 4286.

What I claim as my invention, and desire to secure by letters patent, is making the apertures, O, in the wheel, for the introduction of the water to the buckets, to extend through the outer or cylindrical perimeter thereof, near the top, and then spirally down through, between the buckets, to the bottom thereof, in the manner described, in combination with the funnel-shaped inner rim and curved buckets, as set forth, whether the water be introduced from the inside or outside of the wheel, as before stated.

I also claim the combination of the sliding frame, and segment valves connected therewith, by rods or stems of unequal lengths, for letting on the water by degrees, in the manner set forth.

WILLIAM DRIPPS.

No. 4287.

I claim the mode of producing the camber of the truss, viz: by the distension wedges, or apparatus, as above described, applied between the ends of the bars of the upper stringer, or chord, *in combination* with the contractile and cambering chain, made and applied to the lower or other suitable part of the truss, and operating substantially as above specified.

In testimony whereof, I have hereto set my signature, this eleventh day of September, A. D. 1845.

NATHANIEL RIDER.

No. 4288.

What I claim as my invention, and desire to secure by letters patent, is the method herein described, or any other substantially the same, of indicating the rise and fall of water in a steam boiler or generator, by means of an indicator outside thereof, actuated by a magnet, connected with a float or any other body within the boiler, that rises and falls with the water, and connected with the magnet, substantially as herein described.

GEORGE FABER.

No 4289.

What I claim as my invention, and desire to secure by letters patent, is connecting the cross-head of a reciprocating engine with two crank shafts on opposite sides of, and at equal distances from the centre of vibration, by means of a connecting rod or lever turning on the cross head, and reciprocating with it, and taking hold of the cranks on the two crank shafts, by

which they are caused to turn in opposite directions, and with equal velocities, as herein described.

R. F. LOPER.

No. 4290.

Having thus fully described my improvement, I wish to be understood that I do not claim as my invention the employment of a submerged horizontal wheel within a case in the vessel, as that has before been essayed; but what I do claim as my invention, and desire to secure by letters patent, is the case above described, into which the propellers are inserted, to be placed on the outside of a vessel, of the usual form of sailing vessels, which is independent of and can be taken from said vessel, in combination with a series of horizontal propellers placed one before the other, in the manner set forth.

STEPHEN R. PARKHURST.

No. 4291.

What I claim as my invention, and desire to secure by letters patent, is the manner of attaching pressers to the levers, by the rods and cords, so as to produce the effect above stated.

GREY UTLEY.

No. 4292.

I do not claim adjusting the clevis with a screw and moving swivel hook, as in the "Gallatin plough;" but what I do claim as my invention and improvement, and which I desire to secure by letters patent, is the mode of raising and lowering and confining the ring against the inner side of the front or vertical part of the clevis, by means of a segment grooved wheel, or head, raised and lowered by a vertical screw turning in a female screw, in the upper or horizontal part of the clevis; by which combination and arrangement the weakening of the clevis, arising from the necessity of cutting the usual notches in it for holding the ring, is avoided, and the dropping of the ring is prevented; the said segment grooved wheel holding the ring against the front part of the clevis at the height desired, and made adjustable to any required level, for various depths of ploughing, as set forth.

PATRICK GALLAGHER.

No. 4293.

Having thus described the principle of my invention, and the various modes in which I have contemplated its application, I wish it to be understood that I do not claim the propelling of boats, &c., by the reaction of issuing streams of water, when effected by steam or other power, on the boat, &c.; but what I do claim as my invention, and desire to secure by letters patent, is the method of propelling boats on canals, or cars, or railroads, by means of a column or columns of water discharged from an upper level or reservoir (not in moving with the boat) to a lower level, by means of a syphon or syphons, attached to and moving with the boat, or car, in manner substantially as herein described.

JOSEPHUS ECHOLS.

No. 4294.

Having thus fully described my improvement, what I claim as my invention, and desire to secure by letters patent, is the combination of the above scale of subdivided measures, and the protractor, in the manner described, so that the angles for laying out any sized coat shall be given by the protractor from the points found, by measuring the person to be fitted by means of the scale, as herein set forth.

ABM. A. BOGARDUS.

No. 4295.

What I claim as my invention, and which I desire to secure by letters patent, is preventing the fire and ashes escaping from the stove through the draught openings, by dividing the base or lower box of the stove into a number of apartments, communicating with each other, formed by a horizontal perforated plate and vertical perforated plates, in the manner and for the purpose set forth.

WM. BUTCHER.

No. 4296.

What I claim as my invention, and desire to secure by letters patent, consists in a peculiar manner of working the water ram in combination with the syphon, by the use of a chamber of rarified air, for the purpose of causing the escape-water to flow down the longer leg of the syphon in a continuous stream; also, in the use of channels in the packing of the joints, supplied with water from the air vessel of the ram, for the purpose of excluding, completely and with certainty, the external air from the syphon; also, in the fixtures herein described for the setting in motion and regulating the quantity of water consumed by the ram.

ERASTUS W. ELLSWORTH.

No. 4297.

Having thus explained my invention, I shall claim the plate as combined with the sliding frame for the purpose of receiving the cap plate of any mould of various moulds, as described; also the making the whole frame, plate, toggles, lever, and bars, and rest block of the toggles, adjustable with respect to the mould or bed plates upon which it is placed, in the manner as above described.

In testimony whereof, I have hereto set my signature, this eighteenth day of July, A. D. 1845.

JOSEPH MAGOUN.

No. 4298.

I claim the quadrangular invented pyramidal form of the grate in combination with the side doors, hinged at the bottom and opening downwards, to answer the purpose of hearths, that the whole surface of the fire at the sides may be presented, and the rays therefrom may be cast on to instead of over the article to be cooked or heated on the hearths, as herein de-

scribed. And, finally, I claim the method of sustaining the side doors when open, by means of the jointed and sliding links, as herein described.

C. L. H. WEBB.

No. 4299.

I claim the arrangement of the parts by which I supply the fire with heated air; said arrangment consisting mainly of the sliding register and the plate in front of which the air must descend on its passage to the grate bars. The heating of the admitted air has been attempted under other arrangements, and I limit my claim in this particular, therefore, to the special combination of parts by which I attain this end.

SAMUEL PIERCE.

No. 4300.

In the machine described I claim making the *concave plate or disk* with a concave face and circular opening, provided with a lever and upper lip for the discharge of the cobs, in combination with the sheller and with the shell or bottom, and also the door or valve in the side for the broken cobs, &c.; and also the cylindrical *hopper and spring in combination with the feeder*, as herein described.

THOMAS D. BURRALL.

No. 4301.

Having thus fully described the nature of my improvements in the air-heating furnace, what I claim as new therein, and desire to secure by letters patent, is combining with such a furnace the evaporating and radiating vessels or vessel M, arranged, combined, and operating substantially in the manner and for the purpose herein made known.

EBENEZER BARROWS.

No. 4302.

What I claim as my invention, and desire to secure by letters patent, is making the ends of the fluted, grooved, or ridged ginning rollers, without the flutes, grooves, or ridges, so that they shall run on each other, and thus prevent the injurious action of their parts operating on each other and on the fibres of the cotton, as described.

I claim the rotating, stripping, or cleaning rollers, in combination with the ginning rollers, for the purpose and in the manner substantially as herein described.

I also claim the feeding roller and beater or blower, in combination with the ginning rollers, for the purpose of loosening the cotton, and presenting it to the action of the ginning rollers, as described.

And, finally, I claim the beater or blower, in combination with the ginning rollers, for the purpose and in the manner described.

THEODORE ELY.

No. 4303.

Having thus fully described the manner in which we construct and arrange the various parts of our apparatus for heating apartments, and shown the operation of the same, what we claim therein as new, and desire to secure by letters patent, is the manner of combining and arranging the radiating air heaters so that the air to be heated by them shall ascend on both sides of them, or shell, or case, or casing of brickwork, performing the same office, as set forth; and the fireplace above the top plate being so enclosed by a suitable plate, or by masonry, as to cause the whole of the air heated by the radiators to pass into the apartment, in the manner described.

We do not claim the use of a radiator or radiators, like those marked B, as new, such having been before used; but we limit our claim to that arrangement of them by which they are made to heat an ascending current of air on each of their sides, for the purpose herein fully made known.

We do not intend, however, by this claim, to limit ourselves to the particular form of either of the parts of the said apparatus, but to vary these as we may think proper, whilst we attain the same ends by an arrangement of parts substantially the same.

HENRY KATUSSOWSKI.
J. P. WIERZBICKI.

No. 4304.

Having thus fully described the manner in which I combine the railway and canal for the purpose of transportation, what I claim therein as new, and desire to secure by letters patent, is the combining of a railroad and canal by laying rails on the bottom of the canal, which is to be used, and the rails submerged with its content of water, by the employment of a locomotive engine and of car-boats, which, whilst their wheels are sustained upon the rails, are to be buoyed up by the water, as set forth.

I claim the adapting of the car-boats and the lock chamber to each other, so that when the former are contained within the latter they shall operate as lock gates by preventing or nearly preventing the passage of water, thereby allowing the lock gates to be opened and the train to pass through the lock with little loss of water, upon the principle and substantially in the manner herein described.

SAM'L S. WALLEY.

No. 4305.

What I claim as my invention, and desire to secure by letters patent, is cutting and making the sails of all kinds of vessels with the warp of the cloth and the seams in a horizontal direction, for the purpose and in the manner described.

JAS. MAULL.

No. 4306.

My claims in the above described invention are confined to the filter tube, in combination with the funnel, plunger, spring, and perforated bot-

tom, arranged substantially in the manner and for the purposes herein above described.

WALTER HUNT.

No. 4307.

I do not claim as my invention hanging a gate on a central axis, so as to open in either direction, and close without a return movement, as this has long since been effected; but what I claim as my invention, and desire to secure by letters patent, is such a gate hung and turned on a central axis in combination with the fence arranged around the axis of the gate, and provided with two carriage or other ways on opposite sides, as herein described, and for the purpose specified.

ANDREW HOOD.

No. 4308.

What I claim as my invention, and desire to secure by letters patent, is forming the face of the shuttle cams with a depression, as herein described, to permit the picker to be moved back clear of the shuttle point, after the shuttle has been arrested, and before the shuttle boxes are shifted, as herein described.

ROBERT P. CUNNINGHAM.

No. 4309.

Having thus described my improvement, what I claim as my improvement, and desire to secure by letters patent, is a boiler surrounding a furnace, as herein described, in combination with a flue ascending and returning in an apartment at the foot of the bath, as above set forth.

WM. G. YOUNG.

No. 4310.

I am aware that, for cooking and other purposes, kettles have been set directly into a steam boiler, so as to have the steam in the boiler act directly against their bottoms, but this has always been limited to one kettle for each boiler, which, if applied to the manufacture of sugar, would require one boiler for each kettle in the series, presenting not only the objection of great cost in the original construction, but much labor in attendance, as well as the important difficulty in keeping up an equal temperature under all the kettles at the same time, which is frequently required; and, therefore, I do not wish to claim simply letting a single kettle into a steam boiler, to have the steam act directly on the bottom thereof, nor do I wish to claim simply the insertion of a series of kettles in one boiler for general uses; but what I do claim as my invention, and desire to secure by letters patent, is the arrangement of a series of kettles for evaporating saccharine juices and sirups in the manufacture of sugar, on the top of and let into one steam-boiler, when any method is employed of regulating the temperature of the kettles—that is, reducing or increasing the temperature of a portion of the series without affecting the rest—substantially as herein described.

I also claim arranging the series of evaporating kettles let into the top of

one steam-boiler, to have them exposed directly to the action of steam within the boiler, in combination with the arrangement for heating the pans, for preparing the saccharine juice, by means of steam conducted from the boiler into the double bottoms of the pans, as herein described.

And I also claim dividing the boiler into two or more compartments by a partition or partitions, provided with a valve, in combination with the arrangement of kettles let into the boiler, for the purpose of regulating the temperature, as herein described.

F. DUPLESSIS.

No. 4311.

I do not claim to have invented the mode of causing a circulation of water between a principal boiler of water back and the boiler A, by the pipes *g* and *h*, as this is in common use, neither do I claim to have invented the arrangement or application of the pipes *k* or *l* to the circulation of hot water within a building, except as hereinafter stated; but I do claim as new, and of my own invention—

First. I do not claim to have invented or introduced the pipe to lead in the supply of water from any competent head, but I do claim the mode described of forming this pipe with perforations or orifices near the boiler head, for the purpose of securing the boiler against accidental injury, in the manner and with the effects described and set forth.

Second. I do not claim to have invented the hollow plug of the cock, but I do claim the mode of making and fitting the said plug with the short slots, to draw hot water by the bib, in combination with the long slot, at right-angles with the two former, for the purpose of maintaining a circulation of hot water in the pipes *h* and *l*, or suspending the same by twining the blank part of the plug to the pipes *h* and *l*, substantially as the same are described and shown.

In witness whereof, I have hereunto set my hand, in the city of New York, this thirteenth day of May, one thousand eight hundred and forty-five.

WM. BEEBE.

No. 4312.

Having thus fully set forth the manner in which I arrange and operate a water table or weather strip at the bottoms of doors, what I claim therein as new, and desire to secure by letters patent, is the particular manner in which I have combined the respective parts, as herein described; that is to say, the water table being forced down by the action of the head of the rod on the inclined plane, through the intervention of the levers, and being raised by the spiral springs when the door is opened; and the necessary adjustments being also effected by the aid of the screw nuts and spiral springs, substantially in the manner described.

A. S. PELTON.

No. 4313.

What I claim as my invention, and desire to secure by letters patent, is the manner of restoring hollow cheeks to their natural contour and rotun-

dity by means of metallic bulbs, formed, fitted to, and secured in the mouth, substantially in the manner herein set forth, or by any other attachment between the jaw-bones and the cheek.

JOHN ALLEN.

No. 4314.

What I claim as new, and desire to secure by letters patent, is the method of forming tobacco "lumps" by means of the frame and series of blades, arranged and formed substantially as herein described, in combination with the bed, whereby I save much labor in arranging the tobacco leaves, &c.; and I am enabled to form and press a large number of "lumps" at one operation, to lay the covering smooth and even, give a more perfect form, and discharge them from the moulds in which they have been formed with greater facility than by the old method.

HENRY MOORE.

No. 4315.

What I claim as my invention, and desire to secure by letters patent, is the method of retaining types in their proper relative positions on a cylindrical bed by means of rules or strips of metal, or other appropriate substance, fitting into recesses made for that purpose in the body or stem of types, substantially in the manner described.

RICHARD HEMMING.

No. 4316.

I do not claim to have invented any of the several parts described herein as used by me for these conjoined purposes, as each part, taken separately, is well known.

But I claim as new and of my own invention, and desire to secure by letters patent, the mode of applying the rack frame, and lifting shoe and toothed wheel, to raise the hind wheels from the ground, in combination with the action of the blockers, stays, slide 14, and screw clip 15, to hold the engine in place of working; and I claim the mode described of fitting the arms and the levers, and connecting the same by the crank pin headed screw, to receive the brake rods, and convert the hind wheels into fly wheels, in combination with the described means of connecting the parts with the working pistons, when used for the purpose herein set forth.

In witness whereof, I have hereunto set my hand, in the city of New York, this second day of September, one thousand eight hundred and forty-five.

ERNEST MARX.

No. 4317.

I do not claim as my invention the pistons, valves, or any other known part of the engine, herein before described, nor do I claim the passing the steam from one cylinder to another, that having been done by Wolf, and others; but I claim as my invention, and desire to secure by letters patent, the connecting the pistons of the two cylinders to cranks placed at right angles, in combination with the admitting the steam directly from the boiler into the cylinder only, and the working the steam exhaustively in said cylinder, together with the employing the steam to act simultaneously on both pistons during half the stroke, as hereinbefore described, by opening

a communication alternately, and keeping the same open during only half the stroke between the two cylinders, whilst at all times a vacuum is kept up during the entire stroke in both cylinders, on the opposite sides of each of the pistons to that on which the steam acts.

And I also claim as my invention the momentary stoppage of the exhaust pipe of that cylinder, which receives the steam from that cylinder into a receiver partially filled with tubes, through which the feed water is passed on its way to the boiler, in the manner hereinbefore described.

J. ERICSSON.

No. 4318.

What I claim as my invention, and desire to secure by letters patent, is the new and improved mode, above described, of arranging and adjusting metallic wires, or other conductors to electro magnetic and galvanic telegraph instruments, by which instruments, at opposite extremities of the same, or of a single main wire, or located at distant points on the same main wire, or a single wire, may be kept in constant readiness for use, in conjunction with a galvanic battery, without the necessity of keeping the galvanic circuit closed, or the battery in action, when neither instrument is at work; and by which the battery is put out of action instantly on the ceasing of the motion of the instrument, and in like manner is put into action immediately on commencing the motion of an instrument, and avoiding the disadvantage heretofore experienced in what have been denominated *dependant* circuits, in the working of two or more telegraphic instruments over a single circuit of wire, or of wire and earth conjoined.

E. CORNELL.

No. 4319.

What I claim as my invention, and wish to secure by letters patent, is the mode of holding the rivets in the holes by the use of the springs, in combination with the mandrel or the clamps, in the construction and application, as they are set forth in the accompanying specifications and drawings.

JONATHAN BALL.

No. 4320.

What I claim as my invention, and desire to secure by letters patent, is jointing the sockets that receive the standards of the ploughs to the frame, as herein described, to admit of adjusting in a vertical as well as horizontal direction, as specified; and finally, I claim the method of adjusting the front double tooth by means of the enlarged mortise and wedges, in combination with journal projections on the standards, as described.

ALLEN ELDRED.

No. 4321.

Having thus fully described the manner in which I construct my machine for scraping, smoothing, and shaping ivory comb plates, and other articles of a like character, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged the apparatus for carrying the plates between the cylinders, consisting of the box, the slide, with its piece, and the wheel connected by the rod to the slide,

and to the shaft by the small wheel and the gripe, heretofore described and seen in figs. 1 and 3, operating substantially as before stated.

I claim the manner in which I have arranged the top bed, whereby plates varying in thickness are equally scraped, not reducing the thickness of one more than another; said arrangement consisting of the spring and piece, as seen at figure 5, and the position of said bed, with its space, as seen in figure 7.

I claim the manner in which I have arranged the chisels for scraping, smoothing, and shaping the plate, said arrangements consisting of the levers and the cross-pieces, and the apparatus for securing the chisels to the cross-pieces, seen at figure 8, and for securing the cross pieces to the levers, as seen at figure 1, or at H H, figure 8, and for the movement up or down, for the same, by the screws, as seen at L *i*, L *i*, figure 8.

I claim the manner in which I have arranged the box to receive the plates from the top bed, consisting of the spring on the under side of the lid, seen in figure 6, and the bed, with its tapering rod, clasped by the springs under the said box, operating as before stated.

And I hereby declare that I do not intend by these claims to limit myself to the exact form or arrangement of the respective parts and combinations, as herein described and represented, but to vary these, as I may deem expedient, whilst such arrangements and combinations are substantially the same with those herein fully made known.

CALVIN B. ROGERS.

No. 4322.

Now, the new principle and invention which I, *John W. Wilson*, claim as mine, and which I desire to secure by letters patent, is the *relief truss*, attached to the truss-hoop connecting it, with the mast, to the arm, connecting it with the lever and the yard so as to permit the topmast to be lowered and raised any time at pleasure, through the relief truss, without unshipping the yard, or in anywise interfering with its motions, actions, uses, or any of its appurtenances.

JOHN W. WILSON.

No. 4323.

What I claim as my invention, and desire to secure by letters patent, is the turning of a double seam on the bottom of tin and copper ware, by the application of a bevel wheel on a shaft placed at right-angles with the shaft on which the vessel revolves, in combination with the guide on which the same rests, in order to insure a perfect rotary motion of the vessel.

DANIEL NEWTON.

No. 4324.

I claim as my invention, and wish to secure by letters patent, the combination, herein described, of parts which are designated herein, and marked in the drawings respectively, as follows, viz: the block or platform, the lifter, and the curb or pins 1 and 2; and I claim said combination of the block, lifter, and curb, whether in combination with or without the guide.

JNO. J. HOWE.

No. 4325.

I therefore claim the said inclined rail and slide, as combined with the opening of the puppet head, the same being for the object as above set forth.

In testimony whereof, I have hereto set my signature, this twenty eighth day of August, A. D. 1845.

EZEKIEL PAGE.

No. 4326.

What I claim as my invention, and desire to secure by letters patent, is the use or substitution of tubes made of a material which is a non-conductor of heat, instead of the ordinary metallic tube, between which the wick works up and down, and also the protection of the non-conducting tubes by the cap or prolongation in metal.

I do not claim any particular form of lamp, but simply the application of tubes of a non-conducting material, and the protection of such tubes from the effects of the flame of the lamp. The tubes in question may be applied to lamps of every shape and construction, and my claim is intended to cover such application.

JAMES MACLEAN.

No. 4327.

Having thus fully described the manner in which I construct my coat sector, and also that in which it is applied to the making out for cutting a coat, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged and combined the four arms and the neck slide; the respective arms forming the angles herein designated, or nearly such, and the second and third arms being made to slide upon each other, for the purpose of enlarging or diminishing the profile of the garment to be cut; there being also, on three of those arms, divisions, with marks or numbers corresponding with each other in their general proportion and arrangement, as represented in the drawing, and herein fully described. I will here remark that, although the divisions and numbers marked on the respective arms are considered as useful and convenient for despatch, they are not essential, as the measure taken as herein designated may be applied to the arm, and a mark be made upon it the length of the combined arms. B and C may also be determined by the same measure, and the neck slide also be moved thereby to its proper place, these three measures always being about the same.

ALLEN WARD.

No. 4328.

What I claim as my invention, and desire to secure by letters patent, is the raising spring water to a higher level than its source by the momentum of a running stream of river or other water in contact therewith, in a double ram, constructed as aforesaid, or other ram, constructed and combined substantially in the manner set forth, by which analogous results are produced—the two rams being united by an additional pipe, in which the spring and river water come in contact, as above set forth.

I also claim the combinations and arrangement of the lever, bucket, and

valve, with reservoir, as described, for keeping up the action of the machine. I likewise claim the arrangement of the spring for insuring the opening of the valve, as described.

BENJAMIN S. BENTON.

No. 4329.

Having thus fully described the nature of my improvements in the flouring mill, what I claim therein as new, and desire to secure by letters patent, is the manner in which I have arranged the flights around the bolting reel, in combination with the arrangement of the respective spouts HH and I, and with a device for altering the inclination of the bolting chest and reel, for the purpose set forth. R. C. MAUCK.

No. 4330.

I do not claim the manner of constructing a cast iron or metal railway car wheel, by making it of two covex or concave plates, or one convex and one concave plate, united to a solid or a divided hub, and a circular rim and flanch, as heretofore made; but that which I do claim, is my improved manner of constructing a wheel, by which I am enabled to cast it with a solid hub, and in other respects as I have above set forth, viz: by making it with an *undulating* plate, in combination with a concave or convex plate, or another undulating plate, as herein described.

In testimony whereof, I have hereto set my signature this twenty-third day of August, A. D. 1845.

GEORGE W. EDDY.

No. 4331.

Having thus fully described the nature of my improvement in the steam engine boiler, and shown the operation of the same, what I claim as new therein, and desire to secure by letters patent, is arranging the fire chamber or furnace of a tubular boiler at the side, so that the heat shall act on the upper half of the tubes, in combination with a diaphragm or partition and flue to carry off the flame, heated air, &c., to act on the lower half of the tubes, after acting on the upper half, as described.

And I also claim the making of the bottom of the boiler of a conical or dished form, with a meed or blow off valve in the lowest part of the concavity, in combination with the vertical tubes communicating with the bottom, in the manner herein described, to permit the deposite of the sediment, there being a water space surrounding them to induce circulation of the water up the tubes and down the surrounding space, to wash the sediment towards the meed or blow-off valve, as herein described.

JAS. MONTGOMERY.

No. 4332.

What I claim as my invention, and desire to secure by letters patent, is the combining with the spiral scroll the projecting portion of the buckets, marked X in the drawing; and in combination with the foregoing I claim the arrangement of the buckets, substantially as herein described and set forth. JOHN MECAY.

No. 4333.

What I claim as my discovery, and desire to secure by letters patent, is the before described composition of lime, sand, and charcoal, forming a cement that is impervious to water; that is to say, I claim to have discovered the use of charcoal and stone coal as a component part of plaster or cement, by which it is rendered impervious to water.

W. Y. SINGLETON.

No. 4334.

What I claim as my invention, and desire to secure by letters patent, is the suspension of the upper stone by being firmly fastened to a flange, connected with a hollow spindle through which the mill is fed, said hollow spindle having groovings around its circumference, near each end, fitting the edges of corresponding friction wheels arranged around said spindle, and the arrangement of the segment bar, all in connexion and combination, as aforesaid.

In testimony whereof, I have hereunto subscribed my name, before two witnesses, this third day of October, A. D. 1845.

JOSIAH PLATT.

No. 4335.

What I claim as my improvement, and for which I ask an exclusive right, is my mode of combining and applying two or more cylinders of circular saws, as above described, viz: by alternating large and small saws, and applying them to each other so that a large and small saw shall be opposite, and cut against each other.

In testimony whereof, I, the said Amos Lindsey, hereto subscribe my name, in the presence of the witnesses whose names are hereto subscribed on the second day of August, A. D. 1845.

AMOS LINDSEY.

No. 4336.

What I claim as new in the above described instrument, is the construction of *pockets* in combination with an abdominal *spring pad*, with descending lobes, by which it may be easily adapted to nearly all cases of inguinal hernia, securing a decided advantage over the common truss, by being much easier to the wearer, suiting it to double hernia, and preventing a rupture on the opposite side, which often occurs by wearing the single truss.

I also claim the employment of *rings* to be slipped into the *pockets* of the *front pad*, for encircling the ruptured spot, in order to contract and excite the muscle, thereby disposing the part to heat. The rings may be made of any shape, diameter, or width, that the form or nature of the rupture may require. The instrument I call "*Dr. Fleming's spring pad supporter and truss.*"

LORENZO D. FLEMING.

No. 4337.

Having thus described the nature of my invention, and the best manner I am at present acquainted with for performing the same, I would have it

understood that I make no claim to any of the apparatus herein described; nor do I confine myself thereto, although I consider the means above described the most simple and best for performing the invention.

But what I claim as my invention, is the mode of preserving potatoes in a cooked, or partially cooked state, by means of obtaining the substance of potatoes in a separated or finely divided and dried state, as described.

CHARLES SEPTIMUS EDWARDS.

No. 4338.

I do not claim the supplying the oven with heated air, by means of a flue in contact with the fire chamber; but I do claim the peculiar construction and particular arrangement of the flue in combination with the chamber and pipes, as I have arranged them in my stove, for conveying heated air through the oven, for the purpose of heating the upper part thereof, as described.

SAMUEL MYRES.

No. 4339.

I therefore claim the disk upon the extremity of the lip of the reed, in combination with a corresponding enlargement of the air passage of the reed plate, as described.

Also, bending the stem of the reed at an angle with the lip, and also so bending the same, and in the form of an inverted U; the whole being substantially as above explained.

In testimony that the foregoing is a true description of my said invention and improvement, I have hereto set my signature this eighth day of September, in the year eighteen hundred and forty five.

NATHAN B. JEWETT.

No. 4340.

All that I claim in the before described hive is the construction of the sliding trap, as aforesaid, and the arrangement of the vibrating trap, as aforesaid, for destroying the moth, arranged and operated as set forth.

In testimony whereof, I have hereunto subscribed my name this twentieth day of November, 1845.

JAMES ROBB.

No. 4341.

What I claim as my invention, and desire to secure by letters patent, is the mode of clearing pulp, to be used in the manufacture of paper, from sand, gravel, metallic and other hard and injurious substances, by means of the above described pulp-sand strainer.

WILLIAM BISHOP.

No. 4342.

Having thus fully described the nature and operation of my invention, what I claim as new therein, and desire to secure by letters patent, is the placing an independent set of bearing wheels within the frame of the loco-

motive, revolving loosely upon the main driving shaft, and adapted to an inner extra track of rails, (raised above the main track,) for the purpose of sustaining the weight of the locomotive in ascending or descending inclined planes, lifting the driving wheels from the main track of the rails, and rendering the action of the driving shaft independent of the bearing or driving wheels, when it is desired to transfer the whole power of the locomotive steam engines from the driving wheels to the endless screw, geared to the driving shaft, and its thread working into a rack of friction rollers; the whole arranged, combined, and operating substantially in the manner and for the purpose herein set forth.

EZRA COLEMAN.

No. 4343.

Having thus fully described the construction and operation of my improved bee-hive, what I claim as new therein, and desire to secure by letters patent, is the manner in which the honey or lateral boxes are arranged, in combination with a pyramidal central hive, constructed and operating substantially in the manner and for the purpose herein set forth.

AARON COLTON.

No. 4344.

What I claim as my invention, and desire to secure by letters patent, is the filter, arranged substantially as described, in combination with the cooling chamber surrounding the ice chamber, located and arranged substantially in the manner and for the purpose specified.

JOSEPH T. CRADDOCK.

No. 4345.

The main feature in my said new and improved boom saddle and jaws, which I claim as my invention, and desire to secure by letters patent, is the following, reference being had to the above description and drawings, viz: The method of constructing a saddle so as to leave a space between the mast and saddle, in connexion or combination with the insertion of the slide or slides in the jaws of the boom.

In testimony whereof, I have hereunto set my hand, this nineteenth day of December, A. D. 1845.

JAMES DAVIS, Jr.

No. 4346.

Having now described the construction of the improved machinery to be employed in the manufacture of nails, rivets, screws, and pins, I desire to be understood that I claim, in reference to the heading of metal rods or wire for the above purposes, the means of effecting what I call a "double upset," viz: by crushing the end of the rod or wire for forming the boss or head of the nail, rivet, screw, or pin, by two or more operations of a single heading-punch and pair or set of holding-dies and the sliding guides, the whole in combination as above described; the rod or wire being brought forward between the holding-dies a short distance by the sliding-guides, after the first or partial crushing of the metal has been effected, in order to

supply a sufficient additional quantity of metal to complete and perfect the form of the boss or head when the second pressure of the punch is brought up against it. As respects the pointing of pins, and discharging them from the machine, I claim my improvement therein; the same consisting in imparting to the sliding-bar certain alternating, lateral, and back movements in its bearings, as described, whereby the pins are turned in opposite directions during the action of the mill-roller upon them, and discharged from the machine when the pointing of them has been completed.

In witness whereof, I, the said Samuel Godfrey Reynolds, have hereunto set my hand, this eighteenth day of August, one thousand eight hundred and forty five. S. G. REYNOLDS.

No. 4347.

What I claim as my invention is the mode, herein described, of applying medicated vapors; that is, by submitting the body or parts thereof to the vapor of the substance used, without the presence of steam, by means substantially the same as herein set forth.

BENJ'N SWETT.

No. 67—Reissue.

Having thus fully described my invention and improvements in generating and applying heat, I proceed to specify more particularly what I claim as my invention and improvements.

1st. I claim the collecting and drawing off the combustible gases, chiefly consisting of *carbonic oxide gas*, from blast-and other furnaces, at *one or more points below the top of the fuel in said furnaces*, substantially as set forth in the above specification, for the purpose of employing said gases instead of other fuel for the heating of all kinds of furnaces used in the various processes of manufacturing and working iron and other metals, and for the heating of steam boilers or any other structures requiring a high temperature.

2d. I claim the above described mode, or any other substantially the same, of generating combustible gases from any kind of fuel, in separate furnaces or chambers, and conducting the same to other furnaces or structures that are to be heated by the combustion of said gas.

3d. I claim the above described mode, or any other substantially the same, of forcing, through a system of blowpipes or in any other convenient manner, heated air in numerous small streams, and under a pressure greater than that of the atmosphere, into the same combustible gases in the furnaces or structures, where the same are to be used for the purpose of producing, by the rapid and intimate mixture of the heated air with combustible gases, their immediate and complete combustion.

In testimony whereof, I, the said Christian Edward Detmold, subscribe my name, in the presence of the witnesses whose names are hereto subscribed, on the 8th day of January, A. D. 1845.

C. E. DETMOLD,
Assignee of Wm. Von Faber du Faur.

No. 68.

Having thus fully given an exemplification of the manner in which I

combine and arrange the respective parts of my improvement when applied to a pudding furnace—from which description any competent person will be able to adapt it to other purposes—I wish it understood that I do not claim as my invention the employment of carbonic oxide gas in combination with heated atmospheric air, this being known as the invention of William Von Faber du Faur, upon which this is intended as an improvement; but what I do claim as my invention, is the combination of a reverberatory furnace, having a deep fire-chamber for the special purpose of generating combustible gases from any kind of fuel, as above described, with an arrangement of blowpipes, or other convenient apparatus, through which continuous jets of highly heated atmospheric air are forced into the combustible gases in their passage over the fire-bridge, for the purpose of producing their perfect and rapid combustion, substantially as set forth in the above specification.

In testimony whereof, I, the said Christian Edward Detmold, hereto subscribe my name, in the presence of the witnesses whose names are hereto subscribed, on the eighth day of January, A. D. 1845.

C. E. DETMOLD.

No. 69.

What I claim as new, and desire to secure by letters patent in the above described apparatus, is the combination of the float with the valve, steam engine, and supply pumps, substantially as herein described, so that the depression of the float, caused by a deficiency of water, shall open a valve, and that the steam which escapes through said opening shall drive an engine to operate the supply pumps.

ISAAC N. COFFIN.

No. 70.

Having thus given a full and exact description of the manner of constructing the plough invented by John Deats, and shown the operation thereof, what is claimed therein as constituting his improvements, is—

1st. The manner in which the main land-side piece is combined with the mould-board by means of the piece cast into the land side, and fitting into the recess prepared for it on the front edge of the mould-board, the two parts being drawn together by means of a wedge entering the space, as set forth.

2d. The manner herein set forth of forming and combining the bottom land-side piece, by which form and combination this piece is rendered reversible, and capable of regulating the pitch of the plough, as set forth.

3d. The manner of forming and combining the reversible cutter, extending from point to rear of the upper part of the land side, so as to constitute a part thereof, and being capable of being set forward to any required extent, from the manner in which it is connected to the main land-side piece.

4th. The manner of confining the combined share and point in place, by means of the bolt passing up through the sheath, the bolt, and the recess, and tongue.

5th. The particular manner of combining the clevis with the piece let into the end of the beam, so as to operate in the manner described.

HIRAM DEATS.

No. 71.

Having thus fully described the parts and combinations of parts and operation of the machine for planing, tonguing, and grooving boards or planks, and shown various modes in which the same may be constructed and made to operate without changing the principle or mode of operation of the machine, what is claimed therein as the invention of William Woodworth, deceased, is the employment of rotating planes, substantially as herein described, in combination with rollers, or any analogous device, to prevent the boards from being drawn up by the planes when cutting upwards, or from the reduced, or planed, to the unplaned surface, as described.

And, also, the combination of the rotating planes with the cutter-wheels for tonguing and grooving, for the purpose of planing, tonguing, and grooving boards, &c. at one operation, as described.

And, also, the combination of either the tonguing or the grooving cutter-wheel for tonguing or grooving boards, &c., with the pressure rollers, as described; the effect of the pressure rollers in these operations being such as to keep the boards, &c. steady, and prevent the cutters from drawing the boards towards the centre of the cutter-wheels, whilst it is moved through by machinery in the planing operation: the tendency of the plane is to lift the boards directly up against the rollers; but in the tonguing and grooving, the tendency is overcome by the friction occasioned by the pressure of the rollers.

WILLIAM W. WOODWORTH,
Administrator of William Woodworth, deceased.

Note.—The above claim of William Woodworth's patent (by William W. Woodworth, administrator) was extended by the board of commissioners, under the 18th section of an act of Congress, approved 4th day of July, 1836, for seven years from the 27th day of December, 1842.

And, also, by an act of Congress, approved March 3d, 1845, the above patent is extended seven years from the 27th day of December, 1849.

No. 72.

Having thus fully described the construction and operation of the machinery for manufacturing screw augers, what is claimed therein as new, and desired to be secured by letters patent, is, first, the manner herein described of arranging and combining the shaft, the roller, and the appendages, constituting the machine for twisting the common double twist auger, as set forth, whether the same be made in the precise form described, or in any other that is substantially the same, producing a like effect by like means. Secondly, the manner of forming the lip or lips, and the pintle for the centre worm, either on double or single twist augers, by means of die or swage, combined, arranged, and operating as herein made known.

EZRA L. HOMMEDIEU.

No. 73.

What we claim as our invention, and wish to secure by letters patent, is as follows:

1. We claim the combination of parts, consisting of the wheel, the pintle, and the two distinct bearings, or bearing pieces, said bearing pieces being made as set forth; that is to say, being made in a cylindrical or other anal-

ogous form for the purpose of suiting them to be inserted in a hole, as set forth.

2. We claim the combination of parts, consisting of the wheel, the pintle, and the upper bearing; said pintle and bearing being made and adapted to each other substantially in the manner set forth.

3. We claim the flange on the pintle, located and made thereon in the place and manner and for the purpose set forth.

ELI W. BLAKE.
JOHN A. BLAKE.
PHILOS BLAKE.

No. 74.

What we claim as our invention, and wish to secure by letters patent, is the combining of the pintle directly with the wooden leg of the furniture, without the intervention of the sheath, or other appendage of metal, heretofore employed, the same being done in the manner herein set forth; that is to say, the pintle being made of sufficient length to adapt it to that end, as described, and inserted into a hole in the leg, bored of such depth as that the burden may rest upon the upper end of the pintle.

PHILOS BLAKE.
ELI W. BLAKE.
JOHN A. BLAKE.

No. 75.

Having thus fully set forth the improvements of the said Jonas Rouse, according to the best of our knowledge and belief, what we claim therein as his invention, and desire to secure by letters patent, is the method of turning or bending the tongues of hinge or butt plates, and forming them into eyes, as described, by placing them on a flat surface of a die, having a projection therefrom against which the tongues of the hinge plates are forced by a follower so as to bend them round into eyes, substantially in the manner and for the purpose above specified.

JAMES ROY.
JOHN KNOWER.
BEN. KNOWER.
ANDREW ROY.

No. 76.

What I claim as new in the above described wick, and desire to secure by letters patent, is the lamp-wick made or combined with twine, a strip of tape, muslin, cotton, flannel, or other analogous substance, so as to form the *strip* of a *thin*, *close*, or *hard* substance in the centre for the roller to act upon, and to form a *thick*, *loose*, or open substance of candle-wick, or other analogous material, on each edge or side, for the oil or other fluid to ascend up, in the manner and for the purpose above set forth, or in any other way that is substantially the same.

Witness my hand this fifteenth day of July, A. D. 1845.

SAMUEL RUST.

No. 77.

Having thus fully described my improvement, what I claim as my invention, and desire to secure by letters patent, is elevating the former (properly

shaped, to give the described form to the brim of the hat) from the bench or stand on which it rests, to enable the workman to apply the iron to and turn the edge of the brim, substantially as herein described.

FRANCIS DEGEN.

Patents extended, by act of Congress approved July 4, 1836, *for seven years.*

What I claim as my invention or improvement is the application of the flanches of the wheels on one side of railroad carriages, and of the treads of the wheels on the other side, to turn curves upon railways, particularly such as turning the corners of the streets, wharves, &c., in cities and elsewhere, operating upon the principle herein set forth.

JAMES STIMPSON.

What I claim as my inventions and improvements is the employment of plates or rails, either of cast or wrought-iron, constructed upon the principle or in the manner herein described, having narrow grooves for the flanches to run in, by which they are perfectly adapted to the unobstructed passing of all kinds of carriages used in streets over them; the running of the peripheries of the flanches, or of the cone or rise on the tread of the wheel, upon the rail, in the manner and for the purposes set forth, and the employment of plates upon cast-iron, upon the principle described, for the crossing of gutters and the turning of curves; and I do hereby declare that I do not intend to confine myself to the precise forms and dimensions given, those being intended merely to exemplify, in a clear manner, the nature, object, and mode of carrying into effect my said inventions.

JAMES STIMPSON.

Additional improvements to letters patent.

No. 72.

Having thus fully described my improvements, what I claim as my invention, and desire to secure by this addition to my letters patent, is the combination of the packing springs with the hydrant cock, constructed and arranged substantially in the manner and for the purpose herein set forth.

ROBT. R. COLVIN.

No. 73.

What I claim as my invention, and which I desire to have added to my letters patent, is constructing the rake with an additional head placed in front of and parallel to the rear head, into which the ends of the wire teeth are secured, (as described in my former patent,) and coiling the pieces of wire of which the teeth are composed around the said additional head, and extending down in front of the head in the form of a cima-reversa, or modern scroll, forming the requisite elastic curved teeth for raking the hay, as described.

It will at once be perceived that a greater degree of elasticity is secured to the teeth, while at the same time the strength and utility of the rake are greatly augmented.

HEZEKIAH HAYNES.

No. 74.

And the application of this piece between the inner and outer parts of the thumb bow, for these purposes, constitutes my whole and sole claim in this addition to my original specification and patent.

In witness whereof, I have hereunto set my hand, in the city of New York, this twenty third day of May, one thousand eight hundred and forty-five.

HERMANN WENDT.

No. 75.

What I claim as my invention in the above specified improvement, and desire to secure by letters patent, is to construct the dial in the manner described, so as to give* mean time by the use of the line drawn, as herein set forth.

JAMES P. GARDNER.

No. 76.

What I claim as my invention, and desire to secure by letters patent, as an improvement on the bailing wheel, is the use and construction of the elastic or yielding bucket, with the bulkhead, as herein described.

HORACE D. FORBES.

No. 77.

What I claim as my invention, and desire to have added to my existing patent for an improvement in cooking stoves, consists in the combination of the angular flues with the revertible flue, constructed between the ovens for conducting the draught under the small oven, arranged in the manner and for the purpose set forth; that is to say, for heating the bottom of the small oven without the necessity of passing the draught around the large oven.

WILLIAM L. POTTER.

Designs granted, during the year 1844, *for seven years.*

CLAIMS.

No. 27.

What I claim as my invention, and desire to secure by letters patent, is the design for an ornamental parlour stove, represented in the accompanying drawings.

ADDISON LOW.

No. 28.

What I claim as my invention, and desire to secure by letters patent, is the new shape or configuration produced by forming a trough around the top of the bowl of a glass lamp, and just below the neck of the same, substantially in the manner set forth.

P. F. SLANE.

---

* There is a very small vibration from mean time, only amounting to one minute in something over seventy years.

No. 29.

What is claimed, therefore, as new, and for which I ask a patent, is the peculiar shape or configuration of the combined fire-chamber, radiators, and pedestals, as herein described and represented.

CHARLES S. HINE.

No. 30.

I am fully aware that various articles of metal have been so formed as to have their legs, or other parts, connected together by mechanical arrangements similar to that by which I connect the respective parts of my tripod, and I do not, therefore, claim to have invented anything which could become the subject of a patent for a combination of parts substantially new in their general combination and arrangement, but I limit my claim, as above stated, to the special shape or configuration of the respective parts, as devised by me, and herein set forth.

GILMAN JOSLIN.

No. 31.

What I claim as my invention, and desire to secure by letters patent, is the combination and arrangement of ornamental figures, herein described, forming an ornamental design for a stove. S. H. RANSOM.

No. 32.

What I claim as my invention, and desire to secure by letters patent, is the conformation and arrangement of figures of fruits and foliage, as represented in the annexed drawing.

I do not claim the form or arrangement of the stove, but only the conformation and arrangement of the figures aforesaid.

EZRA RIPLEY.

No. 33.

What I claim as my invention, and desire to secure by letters patent, is the design, shape, configuration, style, and ornamental carvings of the external surface of the plates of the stove. ANSON ATWOOD.

No. 34.

What I claim as original, or as my own invention, is the general design and combination of the several ornamental parts of the stove.

Also, the design of the doors and feet to the stoves; but do not claim to be the inventor of the different parts of the stove, except as above set forth."

DAVID ROOT.

No. 35.

What I claim as my invention, and desire to secure by letters patent, is the ornamental arrangement and form of the sides and ends, and the ornamental part of the bottom, as shown by the drawings. The plan of the top is shown by the dotted line on figure A.

ELIJAH P. PENNIMAN.

No. 36.

What I claim as my invention, and wish to secure by letters patent, is the design, here represented in the drawings and model, of a stand for placing or hanging hats, cloaks, coats, umbrellas, and other articles upon, whether it be made in iron or other metal, composition, wood, or other materials. WILLIAM L. MILLER.

No. 37.

What I claim as my invention, and desire to secure by letters patent, is the combination of figures or ornaments shown in figures 2 and 3, and especially the compositions upon the oven and fire doors.

ADDISON LOW.

No. 38.

And I hereby declare that I am the original producer of the said bust of the Hon. John C. Calhoun, aforesaid, and that I claim to obtain an exclusive property, or right therein to make, use, sell, and vend the same, or copies of the same, to others, or by them to be made and sold.

CLARK MILLS.

No. 39.

What we claim as our invention, and desire to secure by letters patent, is the design, shape, configuration, style, and ornamental carvings of the external surface of the plates of the stoves.

JOHN S. PECKHAM.
MERRITT PECKHAM.

No. 40.

I have thus described and represented the respective parts of my newly designed stove, so far as its configuration and ornament are concerned, and I claim the exclusive right to the use of the plates A and B, thus shaped and ornamented, also in the manner represented in the drawings; and also the particular shape and ornamental design of the top plate thereof, as represented. HENRY STANLEY.

No. 41.

What I claim in my invention, and desire to secure by letters patent, is the peculiar style of ornamental carving on the surface of the plates, and the peculiar elevations and depressions of the surface, as represented in the drawings. EZRA RIPLEY.

No. 42.

What I claim as my invention, is a design of a new and ornamental stove plate, as herein described. CALVIN FULTON.

No. 43.

What I do claim, therefore, is the peculiar carving and combination of figure work and configuration, in such a manner and combination with this particular form of stove, and it is to be expressly understood that I claim nothing more. EZRA RIPLEY.
